

Explicit generators of some pro- p groups via Bruhat-Tits theory

Benoit Loisel

February 21, 2017

Abstract

Given a semisimple group over a local field of residual characteristic p , its topological group of rational points admits maximal pro- p subgroups. Quasi-split simply-connected semisimple groups can be described in the combinatorial terms of valued root groups, thanks to Bruhat-Tits theory. In this context, it becomes possible to compute explicitly a minimal generating set of the (all conjugated) maximal pro- p subgroups thanks to parametrizations of a suitable maximal torus and of corresponding root groups. We show that the minimal number of generators is then linear with respect to the rank of a suitable root system.

1 Introduction

In this paper, a smooth connected affine group scheme of finite type over a field K will be called a K -group. Given a base field K and an K -group denoted by G , we get an abstract group called the group of rational points, denoted by $G(K)$. When K is a non-Archimedean local field, this group inherits a topology from the field. In particular, the topological group $G(K)$ is totally disconnected and locally compact. The maximal compact or pro- p subgroups of such a group $G(K)$, when they exist, provide a lot of examples of profinite groups. Thus, one can investigate maximal pro- p subgroups from the profinite group theory point of view.

1.1 Minimal number of generators

When H is a profinite group, we say that H is **topologically generated** by a subset X if H is equal to its smallest closed subgroup containing X ; such a set X is called a **generating set**. We investigate the minimal number of generators of a maximal pro- p subgroup of the group of rational points of an algebraic group over a local field.

Suppose that $K = \mathbb{F}_q((t))$ is a nonzero characteristic local field, where $q = p^m$ and G is a simple K -split simply-connected K -group of rank l . By a recent result of Capdeboscq and Rémy [CR14, 2.5], we know that any maximal pro- p subgroup of $G(K)$ admits a finite generating set X ; moreover, the minimal number of elements of such a X is $m(l + 1)$.

In the general situation of a smooth algebraic K -group scheme G , we know by [Loi16, 1.4.3] that an algebraic group over a local field admits maximal pro- p subgroups (called pro- p Sylows) if, and only if, it is quasi-reductive (the split unipotent radical is trivial). When K is of characteristic 0, this corresponds to reductive groups because a unipotent group is always split over a perfect field. To provide explicit descriptions of a pro- p Sylow thanks to Bruhat-Tits theory, we restrict the study to the case of a semisimple group G over a local field K .

Such a group G can be decomposed as an almost direct product of almost- K -simple groups. Moreover, by [BoT65, 6.21], we know that for any almost- K -simple simply connected group H , there exists a finite extension of local fields K'/K and an absolutely simple K' -group H' such that H is isomorphic to the Weil restriction $R_{K'/K}(H')$, that means H' seen as a K -group. Since

$H(K) = H'(K')$ by definition of the Weil restriction, we can assume that G is absolutely simple.

In the Bruhat-Tits theory, given a reductive K -group G , we define a polysimplicial complex $X(G, K)$ (a Euclidean affine building), called the Bruhat-Tits building of G over K together with a suitable action of $G(K)$ onto $X(G, K)$. There exists a non-ramified extension K'/K such that the K -group G quasi-splits over K' . There are two steps in the theory. The first part, corresponding to chapter 4 of [BrT84], provides the building $X(G', K')$ of $G_{K'}$ by gluing together affine spaces, called apartments. The second part, corresponding to chapter 5 of [BrT84], applies a Galois descent to the base field K , using fixed point theorems.

In the non quasi-split case, the geometry of the building does not faithfully reflect the structure of the group. There is an anisotropic kernel of the action of $G(K)$ on $X(G, K)$. As an example, when G is anisotropic over K , its Bruhat-Tits building is a point; the Bruhat-Tits theory completely fails to be explicit in combinatorial terms for anisotropic groups. Thus, the general case may require, moreover, arithmetical methods. Hence, to do explicit computations with a combinatorial method based on Lie theory, we have to assume that G contains a torus with enough characters over K . More precisely, we say that a reductive group G is **quasi-split** if it admits a Borel subgroup defined over K or, equivalently, if the centralizer of any maximal K -split torus is a torus [BrT84, 4.1.1].

Now, assume that K is any non-Archimedean local field of residual characteristic $p \neq 2$ and residue field $\kappa \simeq \mathbb{F}_q$ where $q = p^m$. Let G be an absolutely-simple simply-connected quasi-split K -group.

1.1.1 Theorem. *Denote by l the rank of the relative root system of G , and by n the rank of the absolute root system of G . Assume that $l \geq 2$. If G has a relative root system Φ of type G_2 or BC_l , assume that $p \neq 3$. Let P be a maximal pro- p subgroup of $G(K)$. Denote by $d(P)$ the minimal number of generators of P . Then, we have:*

$$d(P) = m(l + 1) \text{ or } m(n + 1)$$

depending on whether the minimal splitting field extension of short roots is ramified or not.

This theorem is formulated more precisely and proven in Corollary 5.2.2. According to [Ser94, 4.2], we know that $d(P)$ can also be computed via cohomological methods: $d(P) = \dim_{\mathbb{Z}/p\mathbb{Z}} H^1(P, \mathbb{Z}/p\mathbb{Z}) = \dim_{\mathbb{Z}/p\mathbb{Z}} \text{Hom}(P, \mathbb{Z}/p\mathbb{Z})$.

From now on, we need to be more explicit. In the following, given a local field L , we denote by ω_L the discrete valuation on L , by \mathcal{O}_L the ring of integers, by \mathfrak{m}_L its maximal ideal, by ϖ_L a uniformizer, and by $\kappa_L = \mathcal{O}_L/\mathfrak{m}_L$ the residue field. Because we have to compare valuations of elements in L^* , we will normalize the discrete valuation $\omega_L : L^* \rightarrow \mathbb{Q}$ so that $\omega_L(L^*) = \mathbb{Z}$. When $l \in \mathbb{R}$, we denote by $\lfloor l \rfloor$ the largest integer less than or equal to l and by $\lceil l \rceil$ the smallest integer greater than or equal to l .

If it is clear in the context, we can omit the index L in these notations. When L/K is an extension, we denote by G_L the extension of scalars of G from K to L . When H is an algebraic L -group, we denote by $R_{L/K}(G)$ the K -group obtained by the Weil restriction functor $R_{L/K}$ defined in [DG70, I§1 6.6].

1.2 Pro- p Sylows and their Frattini subgroups

In a general context, let K be a global field and \mathcal{V} its set of places (i.e. valuations of K). Let $R \leq K$ be a Dedekind domain bounded except over a finite set $\mathcal{S} \subset \mathcal{V}$ of places. For any $v \in \mathcal{V} \setminus \mathcal{S}$, we consider the v -completion R_v of R . We get a first completion $\widehat{G(R)} = \prod_{v \in \mathcal{V} \setminus \mathcal{S}} G(R_v)$. We get a second completion of $G(R)$ by considering its profinite completion denoted by $\widehat{\widehat{G(R)}}$. The *congruence subgroup problem* is to know when the natural map $\widehat{\widehat{G(R)}} \rightarrow \widehat{G(R)}$ is surjective with finite kernel. For example, when $G = \mathrm{SL}_n$ with $n \geq 2$ and $R = \mathbb{Z}$, by a theorem of Matsumoto [Mat69], the surjective map $\widehat{\mathrm{SL}_n(\mathbb{Z})} \rightarrow \prod_p \mathrm{SL}_n(\mathbb{Z}_p)$ has finite kernel if, and only if, $n \geq 3$.

Here, we focus on a single factor and, more precisely, on a pro- p Sylow of a factor $G(R_v)$. More precisely, K is a non-Archimedean local field and G is a semisimple K -group. We consider a maximal pro- p subgroup P of $G(K)$. When G is simply connected, we know by [Loi16, 1.5.3], that there exists a model \mathcal{G} provided by Bruhat-Tits theory, that means a \mathcal{O}_K -group with generic fiber $\mathcal{G}_K = G$, such that we can identify P with the kernel of the natural surjective quotient morphism $\mathcal{G}(\mathcal{O}_K) \rightarrow (\mathcal{G}_\kappa / \mathcal{R}_u(\mathcal{G}_\kappa))(\kappa)$. In another words, the pro- p Sylow P is the inverse image of a p -Sylow among the surjective homomorphism $\mathcal{G}(\mathcal{O}_K) \rightarrow \mathcal{G}(\kappa)$.

To compute the minimal number of generators, the theory of profinite groups provides a method consisting of computing the Frattini subgroup. The Frattini subgroup of a pro- p group P consists of non-generating elements and can be written as $\mathrm{Frat}(P) = \overline{[P, P]P^p}$, the smallest closed subgroup generated by p -powers and commutators of elements of P [DdSMS99, 1.13]. Once the group $\mathrm{Frat}(P)$ has been determined, it becomes immediate to provide a minimal topologically generating set X of P , arising from finite generating set of $P/\mathrm{Frat}(P)$.

From this writing, we observe that the computation of the Frattini subgroup of P is mostly the computation of its derived subgroup. Despite P is close to be an Iwahori subgroup I of $G(K)$ (in fact, $I = \mathcal{N}_{G(K)}(P)$ is an Iwahori subgroup and P has finite index in I), we cannot use the results of [PR84, §6] because there are less toric elements in P than in I . However, computations of Section 4 have some similarities with computations of Prasad and Raghunathan.

We say that P is finitely presented as pro- p group if there exists a closed normal subgroup R of the free pro- p group \widehat{F}_n^p generated by n elements such that $P \simeq \widehat{F}_n^p / R$ and R is finitely generated as a pro- p group. Let $r(P)$ be the minimum of all the $d(R)$ among the R and $n \geq d(P)$. According to [Ser94, 4.3], P is finitely presented as pro- p group if, and only if $H^2(G, \mathbb{Z}/p\mathbb{Z})$ is finite. In this case, we get $r(P) = \dim_{\mathbb{Z}/p\mathbb{Z}} H^2(G, \mathbb{Z}/p\mathbb{Z})$ and, for any R , we have $d(R) = n - d(P) + r(P)$. Note that $r(P)$ does not depend on the choice of a generating set and we can choose simultaneously a minimal generating set and a minimal family of relations. More generally, Lubotzky has shown [Lub01, 2.5] that any finitely presented profinite group P can be presented by a minimal presentation as a profinite group. If we can show that $H^2(G, \mathbb{Z}/p\mathbb{Z})$ is finite, then, by [Wil99, 12.5.8], we get the Golod-Shafarevich inequality $r(P) \geq \frac{d(G)^2}{4}$. This has to be the case according to study of \mathcal{O}_K -standard groups of Lubotzky and Shalev [LS94].

Here, the main result is a description of the Frattini subgroup of P , de-

noted by $\text{Frat}(P)$, in terms of valued root groups datum. We assume that K is a non-Archimedean local field of residue characteristic p and that G is a semisimple and simply-connected K -group. To simplify the statements, we assume, moreover, that G is absolutely almost simple; this is equivalent to assuming that the absolute root system $\tilde{\Phi}$ is irreducible. We know that it is possible to describe a maximal pro- p subgroup P of $G(K)$ in terms of the valued root groups datum [Loi16, 3.2.9]. A maximal poly-simplex of the building $X(G, K)$, seen as poly-simplicial complex, is called an alcove. We denote by \mathbf{c}_{af} a well-chosen alcove to be a fundamental domain of the action of $G(K)$ on $X(G, K)$. Any maximal pro- p subgroup of $G(K)$ fixes a unique alcove. Up to conjugation, we can assume that $\mathbf{c} = \mathbf{c}_{\text{af}}$ is the only alcove fixed by P . It is then possible to describe the Frattini subgroup in terms of the valued root groups datum, as stated in the following two theorems:

1.2.1 Theorem. *We assume that $p \neq 2$ and, if Φ is of type G_2 or BC_l , we assume that $p \geq 5$.*

Then the pro- p group P is topologically of finite type and, in particular, $\text{Frat}(P) = P^p[P, P]$. Moreover, when K is of characteristic $p > 0$, we have $P^p \subset [P, P]$.

The Frattini subgroup $\text{Frat}(P)$ can be written as a directly generated product in terms of the valued root groups datum.

When Φ is reduced (that means is not of type BC_l), then $\text{Frat}(P)$ is the maximal pro- p subgroup of the pointwise stabilizer in $G(K)$ of the combinatorial ball centered at \mathbf{c} of radius 1.

For a more precise version, see Theorems 5.1.1 and 5.1.2.

1.3 Structure of the paper

We assume that G is a simply-connected quasi-split semisimple K -group. We fix a maximal Borel subgroup B of G defined over K . In particular, this choice determines an order Φ^+ of the root system and a basis Δ . By [Bor91, 20.5, 20.6 (iii)], there exists a maximal K -split torus S in G such that its centralizer, denoted by $T = \mathcal{Z}_G(S)$, is a maximal K -torus of G contained in B . We fix a separable closure K_s of K ; by [Bor91, 8.11], there exists a unique smallest Galois extension of K , denoted by \tilde{K} , splitting T , hence also splitting G by [Bor91, 18.7]. We call **the relative root system**, denoted by Φ , the root system of G relatively to S . We call **the absolute root system**, denoted by $\tilde{\Phi}$, the root system of $G_{\tilde{K}}$ relatively to $T_{\tilde{K}}$. In Section 2.1.2, we define a $\text{Gal}(\tilde{K}_s/K)$ -action on $\tilde{\Phi}$ which preserves the Dynkin diagram structure of $\text{Dyn}(\tilde{\Delta})$ and on its basis $\tilde{\Delta}$ corresponding to the Borel subgroup B . According to [BrT84, 4.2.23], when G is absolutely simple (hence $\text{Dyn}(\tilde{\Delta})$ is connected), the group $\text{Aut}(\text{Dyn}(\tilde{\Delta}))$ is a finite group of order $d \leq 6$. As a consequence, the degree of each splitting field extension is small and does not interact a lot with Lie theory. One can note that a major part of proofs in this paper is taken by the non-reduced BC_l cases and the trialitarian D_4 cases.

From this action and thanks to a rank 1 consideration, we define, according to [BrT84, §4.2], a coherent system of parametrizations of root groups in Section 2.1.3 together with a filtration of the root groups in Section 2.1.4. This provides us a generating valued root groups datum $(T(K), (U_a(K), \varphi_a)_{a \in \Phi})$ built from (G, S, K, \tilde{K}) . This filtration corresponds to a prescribed affinisation of the spherical root system Φ . From this, we compute, in Sections 2.2 and 2.3,

various commutation relations between unipotent and semisimple elements in rank 1. This will be useful to describe, in Section 3.2, the action of P onto a combinatorial ball centered at \mathbf{c} of radius 1. This will also be useful in Section 5.1 to generate semisimple elements of $\text{Frat}(P)$.

We denote by $\mathbb{A} = A(G, S, K)$ the “standard” apartment and we choose a fundamental alcove $\mathbf{c}_{\text{af}} \subset \mathbb{A}$, to be a fundamental domain of the action of $G(K)$ on $X(G, K)$. Those objects will be described in Section 3.1.1 and 3.1.2 respectively thanks to the sets of values, defined in Section 2.1.5, which measure where the gaps between two terms of the filtration are and, in the non-reduced case, what kind of gaps we must deal with. From this, we deduce, in Section 3.1.3, the geometrical description of the combinatorial ball centered at \mathbf{c} of radius 1. Consequently, the geometric situation provides, in Section 3.2, an upper bound for $\text{Frat}(P)$, that means a group Q containing $\text{Frat}(P)$.

Thus, we seek a generating set of Q contained in $\text{Frat}(P)$. From the writing $\text{Frat}(P) = \overline{P^p[P, P]}$, we seek such a generating set by commuting elements of P . In Section 4.1, we invert the commutation relations provided by [BrT84, A] in the quasi-split case from which we deduce, in Section 4.2, a list of unipotent elements contained in $[P, P]$.

From these unipotent elements and from semisimple elements obtained by the rank 1 case, we obtain, in Section 5.1, a generating set and a description of the Frattini subgroup as a directly generated product. In Section 3.1.3, we go a bit further than Bruhat-Tits in the study of quotient subgroups of filtered root groups. From this, we can compute the finite quotient $P/\text{Frat}(P)$ and deduce, in Section 5.2, a minimal generating set of P . The minimal number of elements of such a family is stated in Corollary 5.2.2.

We summarize this in the following graph:

2 Rank 1 subgroups inside a valued root group datum

We keep notations of Section 1.3. In particular, we always denote by K a field and by G a semisimple K -group. From Section 2.1.4, we will assume that K is a non-Archimedean local field, and we will assume that G is simply-connected, almost- K -simple. In order to compute the Frattini subgroup of a maximal pro- p subgroup of $G(K)$, we adopt the point of view of valued root groups datum. In Section 2.1, we recall how we define a valuation on root groups, and how these groups can be parametrized. Thanks to these

parametrizations, given in Section 2.1.3, we compute explicitly, in Sections 2.2 and 2.3, the various possible commutators, and the p -powers of elements in a rank 1 subgroup corresponding to a given root. The rank 1 case is not only useful to define filtrations of root groups, but also useful to compute elements in the Frattini subgroup corresponding to elements of the maximal torus T . There are exactly two root systems, up to isomorphism, whose types are named A_1 and BC_1 , corresponding to groups SL_2 (Section 2.2) and $SU(h) \subset SL_3$ (Section 2.3) respectively.

We denote by $T(K)_b$ the maximal bounded subgroup of $T(K)$, defined in [BrT84, 4.4.1]. We denote by $T(K)_b^+$ the (unique) maximal pro- p subgroup of $T(K)_b$.

2.1 Valued root groups datum

We want to describe precisely the derived group of a maximal pro- p subgroup. We do it in combinatorial terms, thanks to a filtration of root groups. Because we have to deal with non-reduced root systems, we recall the following definitions:

2.1.1 Definition. Let Φ be a root system. A root $a \in \Phi$ is said to be **multipliable** if $2a \in \Phi$; otherwise, it is said to be **non-multipliable**. A root $a \in \Phi$ is said to be **divisible** if $\frac{1}{2}a \in \Phi$; otherwise, it is said to be **non-divisible**.

The set of non-divisible roots, denoted by Φ_{nd} , is a root system; the set of non-multipliable roots, denoted by Φ_{nm} , is a root system.

2.1.1 Root groups datum

For each root $a \in \Phi$, there is a unique unipotent subgroup U_a of G whose Lie algebra is a weight subspace with respect to a . In order to define an action of $G(K)$ on a spherical building with suitable properties, it suffices to have suitable relations of the various root groups $U_a(K)$. These required relations are the axioms given in the definition of a root groups datum. More precisely:

2.1.2 Definition. [BrT72, 6.1.1] Let G be an abstract group and Φ be a root system. A **root groups datum** of G of type Φ is a system $(T, (U_a, M_a)_{a \in \Phi})$ satisfying the following axioms:

- (RGD 1) T is a subgroup of G and, for any $a \in \Phi$, the set U_a is a non-trivial subgroup of G , called the root group of G associated to a .
- (RGD 2) For any $a, b \in \Phi$, the group of commutators $[U_a, U_b]$ is contained in the group generated by the groups U_{ra+sb} where $r, s \in \mathbb{N}^*$ and $ra+sb \in \Phi$.
- (RGD 3) If a is a multipliable root, we have $U_{2a} \subset U_a$ and $U_{2a} \neq U_a$.
- (RGD 4) For any $a \in \Phi$, the set M_a is a right coset of T in G and we have $U_{-a} \setminus \{1\} \subset U_a M_a U_a$.
- (RGD 5) For any $a, b \in \Phi$ and $n \in M_a$, we have $nU_b n^{-1} = U_{r_a(b)}$ where $r_a \in W(\Phi)$ is the orthogonal reflection with respect to a^\perp and $W(\Phi)$ is the Weyl group of Φ .
- (RGD 6) We have $TU_{\Phi^+} \cap U_{\Phi^-} = \{1\}$ where Φ^+ is an order of the root system Φ and $\Phi^- = -\Phi^+ = \Phi \setminus \Phi^+$.

A root groups datum is said to be **generating** if the groups U_a and T generate G .

Now, given a reductive group G over a field K , with a relative root system Φ , we provide a root groups datum of $G(K)$. Let $a \in \Phi$. By [Bor91, 14.5 and 21.9], there exists a unique closed K -subgroup of G , denoted by U_a , which is connected, unipotent, normalized by T and whose Lie algebra is $\mathfrak{g}_a + \mathfrak{g}_{2a}$. This group U_a is called the **root group** of G associated to a . By [BrT84, 4.1.19], there exists cosets M_a such that $(T(K), (U_a(K), M_a)_{a \in \Phi})$ is a generating root groups datum of $G(K)$ of type Φ .

2.1.2 The $*$ -action on the absolute root system and splitting extension fields of root groups

From now on, G is a quasi-split semisimple group. As in Section 1.3, we denote by \tilde{K} the minimal splitting field of G over K (uniquely defined in a given separable closure K_s of K).

In a general context, there is a canonical action of the absolute Galois group $\Sigma = \text{Gal}(K_s/K)$ on the algebraic group G . When G is quasi-split, we can choose a maximal K -split torus S and we get a maximal torus $T = \mathcal{Z}_G(S)$ of G defined over K . Thus, we define an action of Σ on $X^*(T_{K_s})$ by:

$$\forall \sigma \in \Sigma, \forall \chi \in X^*(T_{K_s}), \sigma \cdot \chi = t \mapsto \sigma(\chi(\sigma^{-1}(t)))$$

In the same way, thanks to conjugacy of minimal parabolic subgroups (which are Borel subgroups when G is quasi-split), we define an action of Σ on the type of parabolic subgroups, from which we deduce an action on the (simple) absolute roots.

2.1.3 Notation (The $*$ -action on the absolute root system). This is a summary of [BoT65, §6] for a quasi-split group G . In particular, there exists a Borel subgroup B of G defined over K . Denote by $\tilde{\Delta}$ the set of absolute simple roots and by $\text{Dyn}(\tilde{\Delta})$ its associated Dynkin diagram. There exists an action of the Galois group $\Sigma = \text{Gal}(\tilde{K}/K)$ on $\text{Dyn}(\tilde{\Delta})$ which preserves the diagram structure. This action is called the $*$ -action and it can be extended, by linearity, to an action of Σ on $\tilde{V}^* = X^*(T_{\tilde{K}}) \otimes_{\mathbb{Z}} \mathbb{R}$, and on $\tilde{\Phi}$. The restriction morphism $j = \iota^* : X^*(T) \rightarrow X^*(S)$, where $\iota : S \subset T$ is the inclusion morphism, can be extended to an endomorphism of the Euclidean space $\rho : \tilde{V}^* \rightarrow \tilde{V}^*$. This morphism ρ is the orthogonal projection onto the subspace V^* of fixed points by the action of Σ on \tilde{V}^* . From a geometric realization of $\tilde{\Phi}$ in the Euclidean space \tilde{V}^* , we deduce a geometric realization of $\Phi = \rho(\tilde{\Phi})$ in V^* . The orbits of the action of Σ on $\tilde{\Phi}$ are the fibers of the map $\rho : \tilde{\Phi} \rightarrow \Phi$.

2.1.4 Notation (Some field extensions). According to [BrT84, 4.1.2], by definition of \tilde{K} as minimal splitting extension, the $*$ -action of $\Sigma = \text{Gal}(\tilde{K}/K)$ on $\text{Dyn}(\tilde{\Delta})$ is faithful. Assume that G is almost- K -simple, so that the relative root system Φ is irreducible. Consider a connected component of $\text{Dyn}(\tilde{\Delta})$. Denote by Σ_0 its pointwise stabilizer in Σ . Denote by Σ_d its setwise stabilizer, where $d \in \mathbb{N}^*$ is defined by $d = [\Sigma_d : \Sigma_0]$. We denote $L_d = \tilde{K}^{\Sigma_d}$ and $L_0 = \tilde{K}^{\Sigma_0}$, so that L_0/L_d is a Galois extension of degree d . Because of the classification of root systems, the index d is an element of $\{1, 2, 3, 6\}$.

If $d = 2$, we let $L' = L_0$; we fix $\tau \in \text{Gal}(L_0/L_d)$ to be the non-trivial element.

If $d \geq 3$, we let L' be a separable sub-extension of L_0 (possibly non-Galois) of degree 3 over L_d ; we fix $\tau \in \text{Gal}(L_0/L_d)$ to be an element of order 3.

Thus, we denote $d' = [L' : L_d] \in \{1, 2, 3\}$. In practice, $d' = \min(d, 3)$.

2.1.5 Remark. According to [BoT65, 6.21], we can write $G = R_{L_d/K}(G')$ where G' is an absolutely simple L_d -group. Hence $G(K) \simeq G'(L_d)$. Because, in this paper, we prove some results on rational points, we could assume that G is absolutely simple. Under this assumption, the root system $\tilde{\Phi}$ is irreducible; $\tilde{K} = L_0$ and $L_d = K$. Despite this, we will only assume that G is K -simple in order to have more intrinsic statements.

2.1.6 Definition. Let $\alpha \in \tilde{\Phi}$ be an absolute root. Denote by Σ_α be the stabilizer of α for the $*$ -action. The **field of definition** of the root α is the subfield of \tilde{K} fixed by Σ_α , denoted by $L_\alpha = \tilde{K}^{\Sigma_\alpha}$.

Let $a = \alpha|_S$. The **splitting field extension class** of a is the isomorphism class of the field extension L_α/K , denoted by L_a/K .

Proof that this definition makes sense. We know, by [BoT65, §6], that the set $\{\alpha \in \tilde{\Phi}, a = \alpha|_S\}$ is a non-empty orbit of the $*$ -action on $\tilde{\Phi}$. Hence, by abuse of notation, we denote $a = \{\alpha \in \tilde{\Phi}, a = \alpha|_S\}$. Thus, given any relative root $a \in \Phi$, the field extension class L_α/K does not depend of the choice of $\alpha \in a$. \square

2.1.7 Remark. If $a \in \Phi$ is a multipliable root, then there exists $\alpha, \alpha' \in a$ such that $\alpha + \alpha' \in \tilde{\Phi}$. Because a is an orbit, we can write $\alpha' = \sigma(\alpha)$ where $\sigma \in \Sigma$. As a consequence, the extension of fields $L_\alpha/L_{\alpha+\alpha'}$ is quadratic. By abuse of notation, we denote this extension class by L_a/L_{2a} ; the ramification of this extension will be considered later.

2.1.3 Parametrization of root groups

In order to value the root groups (we do it in Section 2.1.4) thanks to the valuation of the local field, we have to define a parametrization of each root group. Moreover, these valuations have to be compatible. That is why we furthermore have to get relations between the parametrizations.

Let $(\tilde{x}_\alpha)_{\alpha \in \tilde{\Phi}}$ be a Chevalley-Steinberg system of $G_{\tilde{K}}$. This is a parametrization of the absolute root groups $\tilde{x}_\alpha : U_\alpha \rightarrow \mathbb{G}_a$ satisfying some compatibility relations, that will be exploited to get commutation relations in Section 4.1. We recall the precise definition and that such a system exists in Section 4.1).

Let $a \in \Phi$ be a relative root. To compute commutators between elements of opposite root groups, or between elements of a torus and of a root group, it is sufficient to compute inside the simply-connected semisimple K -group $\langle U_{-a}, U_a \rangle$ generated by the two opposite root groups U_{-a} and U_a . Let $\pi : G^a \rightarrow \langle U_{-a}, U_a \rangle$ be the universal covering of the quasi-split semisimple K -subgroup of relative rank 1 generated by U_a and U_{-a} . The group G^a splits over L_a (this explains the terminology of “splitting field” of a root). A parametrization of the simply-connected group G^a is given by [BrT84, 4.1.1 to 4.1.9]. We now recall notations and the matrix realization that we will use later.

The non-multipliable case: Let $a \in \Phi$ be a relative root such that $2a \notin \Phi$. By [BrT84, 4.1.4], the rank 1 group G^a is isomorphic to $R_{L_\alpha/K}(\text{SL}_{2,L_\alpha})$. It can be written as $G^a = R_{L_\alpha/K}(\tilde{G}^\alpha)$ with an isomorphism $\xi_\alpha : \text{SL}_{2,L_\alpha} \xrightarrow{\sim} \tilde{G}^\alpha$.

Inside the classical group SL_{2,L_α} , a maximal L_α -split torus of SL_{2,L_α} can be parametrized by the following homomorphism:

$$\begin{aligned} z : \mathbb{G}_{m,L_\alpha} &\rightarrow \mathrm{SL}_{2,L_\alpha} \\ t &\mapsto \begin{pmatrix} t & 0 \\ 0 & t^{-1} \end{pmatrix} \end{aligned}$$

The corresponding root groups can be parametrized by the following homomorphisms:

$$\begin{aligned} y_- : \mathbb{G}_{a,L_\alpha} &\rightarrow \mathrm{SL}_{2,L_\alpha} & y_+ : \mathbb{G}_{a,L_\alpha} &\rightarrow \mathrm{SL}_{2,L_\alpha} \\ v &\mapsto \begin{pmatrix} 1 & 0 \\ -v & 1 \end{pmatrix} & \text{and} & u &\mapsto \begin{pmatrix} 1 & u \\ 0 & 1 \end{pmatrix} \end{aligned}$$

According to [BrT84, 4.1.5], there exists a unique L_α -group homomorphism, denoted by $\xi_\alpha : \mathrm{SL}_{2,L_\alpha} \rightarrow \tilde{G}^\alpha$, satisfying $\tilde{x}_{\pm\alpha} = \pi \circ \xi_\alpha \circ y_\pm$.

Thus, we define a K -homomorphism $x_a = \pi \circ R_{L_\alpha/K}(\xi_\alpha)$ which is a K -group isomorphism between $R_{L_\alpha/K}(\mathbb{G}_{a,L_\alpha})$ and U_a . We also define the following K -group isomorphism:

$$\tilde{a} = \pi \circ R_{L_\alpha/K}(\xi_\alpha \circ z) : R_{L_\alpha/K}(\mathbb{G}_{m,L_\alpha}) \rightarrow T^a$$

where $T^a = T \cap G^a$.

The multipliable case: Let $a \in \Phi$ be a relative root such that $2a \in \Phi$. Let $\alpha \in a$ be an absolute root from which a arises, and let $\tau \in \Sigma$ be an element of the Galois group such that $\alpha + \tau(\alpha)$ is again an absolute root. To simplify notations, we let (up to compatible isomorphisms in Σ) $L = L_a = L_\alpha$ and $L_2 = L_{2a} = L_{\alpha+\tau(\alpha)}$. By [BrT84, 4.1.4], the K -group G^a is isomorphic to $R_{L_2/K}(\mathrm{SU}(h))$, where h denotes the hermitian form on $L \times L \times L$ given by the formula:

$$h : (x_{-1}, x_0, x_1) \mapsto \sum_{i=-1}^1 x_i^\tau x_{-i}$$

The group $G_{L_2}^a$ can be written as $G_{L_2}^a = \prod_{\sigma \in \mathrm{Gal}(L_2/K)} \tilde{G}^{\sigma(\alpha), \sigma(\tau(\alpha))}$ where each $\tilde{G}^{\sigma(\alpha), \sigma(\tau(\alpha))}$ denotes a simple factor isomorphic to $\mathrm{SU}(h)$, so that $\mathrm{SU}(h)_L \simeq \mathrm{SL}_{3,L}$.

We define a connected unipotent L_2 -group scheme by providing the L_2 -subvariety $H_0(L, L_2) = \{(u, v) \in L \times L, u^\tau u = v + {}^\tau v\}$ of $L_a \times L_a$ with the following group law:

$$(u, v), (u', v') \mapsto (u + u', v + v' + u^\tau u')$$

Then, we let $H(L, L_2) = R_{L_2/K}(H_0(L, L_2))$. For the rational points, we get $H(L, L_2)(K) = \{(u, v) \in L \times L, u^\tau u = v + {}^\tau v\}$ and the group law is given by $x_a(u, v)x_a(u', v') = x_a(u + u', v + v' + u^\tau u')$.

2.1.8 Notation. For any multipliable root $a \in \Phi$, in [BrT84, 4.2.20] are furthermore defined the following notations:

- $L^0 = \{y \in L, y + {}^\tau y = 0\}$, this is an L_2 -vector space of dimension 1;
- $L^1 = \{y \in L, y + {}^\tau y = 1\}$, this is an L^0 -affine space.

Indeed, if K is not of characteristic 2, then $L^0 = \ker(\tau + \mathrm{id})$ is of dimension 1 because $L_2 = \ker(\tau - \mathrm{id})$ is of dimension 1 and ± 1 are the eigenvalues of $\tau \in \mathrm{GL}(L_a)$. Moreover, the affine space L^1 is non-empty because it contains $\frac{1}{2}$. If K is of characteristic 2, then $L^0 = \ker(\tau + \mathrm{id}) = L_2$.

2.1.9 Remark (Interest of such notations). For any $\lambda \in L^0$ so that $\lambda \neq 0$, we have an isomorphism of abelian groups given by the relation $\begin{matrix} L_2 & \rightarrow & L^0 \\ y & \mapsto & \lambda y \end{matrix}$, so that $x_a(0, \lambda y) = x_{2a}(y)$. This constitutes an additional uncertainty when we want to perform computations in $G(K)$. Because of valuation considerations, we will have to choose a λ whose valuation is equal to zero; in fact, this is always possible. To avoid confusion, it is better to work with the isomorphism of abelian groups $\begin{matrix} L_a^0 & \rightarrow & U_{2a}(K) \\ y & \mapsto & x_a(0, y) \end{matrix}$ in order to realize this group as a subgroup of $U_a(K)$.

The affine space L^1 has an interest in the context of a valued field. In particular, as soon as we will know that L^1 is non-empty, we will write $L = L_2\lambda \oplus L^0$ with a suitable $\lambda \in L^1$.

We parametrize a maximal torus of $SU(h)$ by the isomorphism

$$\begin{aligned} z : R_{L/L_2}(\mathbb{G}_{m,L}) &\rightarrow SU(h) \\ t &\mapsto \begin{pmatrix} t & 0 & 0 \\ 0 & t^{-1}\tau t & 0 \\ 0 & 0 & \tau t^{-1} \end{pmatrix} \end{aligned}$$

We parametrize the corresponding root groups of $SU(h)$ by the homomorphisms:

$$\begin{aligned} y_- : H_0(L, L_2) &\rightarrow SU(h) \\ (u, v) &\mapsto \begin{pmatrix} 1 & 0 & 0 \\ u & 1 & 0 \\ -v & -\tau u & 1 \end{pmatrix} \end{aligned}$$

and

$$\begin{aligned} y_+ : H_0(L, L_2) &\rightarrow SU(h) \\ (u, v) &\mapsto \begin{pmatrix} 1 & -\tau u & -v \\ 0 & 1 & u \\ 0 & 0 & 1 \end{pmatrix} \end{aligned}$$

By [BrT84, 4.1.9], there exists a unique L_2 -group isomorphism, denoted by $\xi_\alpha : SU(h) \rightarrow \tilde{G}^{\alpha, \tau(\alpha)}$, satisfying $\tilde{x}_{\pm\alpha} = \pi \circ \xi_\alpha \circ y_\pm$. From this, we define a K -homomorphism $x_a = \pi \circ R_{L_2/K}(\xi_\alpha)$ which is a K -group isomorphism between the K -group $H(L, L_2)$ and the root group U_a . We also define the following K -group isomorphism:

$$\tilde{a} = \pi \circ R_{L_2/K}(\xi_\alpha \circ z) : R_{L_\alpha/K}(\mathbb{G}_{m,L_\alpha}) \rightarrow T^a$$

where $T^a = T \cap G^a$.

2.1.4 Valuation of a root groups datum

For each root group, we now use its parametrization to define an exhaustion by subgroups. In order to define an action of $G(K)$ on an affine building with suitable properties, it suffices to have suitable relations between the terms of filtration of root groups. More precisely:

2.1.10 Definition. [BrT72, 6.2.1] Let G be an abstract group, let Φ be a root system and let $(T, (U_a, M_a)_{a \in \Phi})$ be a root groups datum of G of type Φ . A **valued root groups datum** is a system $(T, (U_a, M_a, \varphi_a)_{a \in \Phi})$, where each φ_a is a map from U_a to $\mathbb{R} \cup \{\infty\}$, satisfying the following axioms:

- (VRGD 0) for any $a \in \Phi$, the image of φ_a contains at least 3 elements;
- (VRGD 1) for any $a \in \Phi$ and any $l \in \mathbb{R} \cup \{\infty\}$, the set $U_{a,l} = \varphi_a^{-1}([l; \infty])$ is a subgroup of U_a and the group $U_{a,\infty}$ is $\{1\}$;
- (VRGD 2) for any $a \in \Phi$ and any $m \in M_a$, the map $u \mapsto \varphi_{-a}(u) - \varphi_a(mum^{-1})$ is constant over $U_{-a} \setminus \{1\}$;
- (VRGD 3) for any $a, b \in \Phi$ such that $b \notin -\mathbb{R}_+a$ and any $l, l' \in \mathbb{R}$, the group of commutators $[U_{a,l}, U_{b,l'}]$ is contained in the group generated by the groups $U_{ra+sb, rl+sl'}$ where $r, s \in \mathbb{N}^*$ and $ra + sb \in \Phi$;
- (VRGD 4) for any multipliable root $a \in \Phi$, the map φ_{2a} is the restriction of the map $2\varphi_a$ to the subgroup U_{2a} ;
- (VRGD 5) for any $a \in \Phi$, any $u \in U_a$ and any $u', u'' \in U_{-a}$ such that $u'uu'' \in M_a$, we have $\varphi_{-a}(u') = -\varphi_a(u)$.

Now, given a reductive group G over a non-Archimedean local field K , with a relative root system Φ , we provide a valued root groups datum of $G(K)$. We define a filtration $(\varphi_a)_{a \in \Phi}$ of the rational points $U_a(K)$ of each root group by:

- $\varphi_a(x_a(y)) = \omega(y)$ if a is a non-multipliable and non-divisible root, and if $y \in L_a$;
- $\varphi_a(x_a(y, y')) = \frac{1}{2}\omega(y')$ if a is a multipliable root and if $(y, y') \in H(L_a, L_{2a})$;
- $\varphi_{2a}(x_a(0, y')) = \omega(y')$ if a is a multipliable root and if $y' \in L_a^0$.

By [BrT84, §4.2], the family $(T, (U_a(K), M_a, \varphi_a)_{a \in \Phi})$ is a valued root groups datum.

2.1.5 Set of values

If L/K is a finite extension of local fields, the valuation ω over K^\times can be extended uniquely to a valuation over L^\times , still denoted by ω because of its uniqueness. We let $\Gamma_L = \omega(L^\times)$.

Because we considered a discrete valuation ω , the terms of filtration indexed by \mathbb{R} can, in fact, be indexed by discrete subsets. These subsets will be used in Section 3.1, to provide an “affinisation” of the spherical root system.

Let $a \in \Phi$ be a root. We define the following sets of values:

- $\Gamma_a = \varphi_a(U_a(K) \setminus \{1\})$;
- $\Gamma'_a = \{\varphi_a(u), u \in U_a(K) \setminus \{1\} \text{ and } \varphi_a(u) = \sup \varphi_a(uU_{2a}(K))\}$.

Furthermore, for any value $l \in \mathbb{R}$, we denote $l^+ = \min\{l' \in \Gamma_a, l' > l\}$. This is the lowest value, greater than l , for which we detect a change in the valued root groups $(U_{a,l'})_{l' > l}$. In order to characterize Γ'_a , we complete the notations of 2.1.8 introducing the following $L_{a,\max}^1 = \{z \in L_a^1, \omega(z) = \sup\{\omega(y), y \in L_a^1\}\}$. It is the subset of L_a^1 whose elements reach the maximum of the valuation.

2.1.11 Remark. Be careful that the value l^+ also depends on a .

The sense of Γ'_a will be provided by Lemma 3.1.13, as the set of values parametrizing the affine roots.

2.1.12 Lemma. *If a is a non-multipliable non-divisible root, then we have $\Gamma_a = \Gamma'_a = \Gamma_{L_a}$.*

Proof. This is obvious by the isomorphism between $U_a(K)$ and L_a . □

Now, we assume that $a \in \Phi$ is a multipliable root.

Let p be the residue characteristic of K . Even if the sets of values can be computed for any p , we assume here that $p \neq 2$. This assumption provides a short cut in the computation of sets of values (mostly because $\frac{1}{2} \in L_{a,\max}^1$ in this case), and will be necessary later for more algebraic reasons.

Since ω is a discrete valuation and since for any $y \in L_a^1$, we have $\omega(y) \leq 0$, it is clear that $L_{a,\max}^1$ is non-empty. Moreover, when $p \neq 2$, we have $\frac{1}{2} \in L_{a,\max}^1$. Hence, by [BrT84, 4.2.21 (4)], we know that $\Gamma_a = \frac{1}{2}\Gamma_{L_a}$ and that $\Gamma'_a = \Gamma_{L_a}$.

By [BrT84, 4.3.4], we know that:

- when the quadratic extension L_a/L_{2a} is unramified, we have the equalities $\Gamma_{2a} = \Gamma'_{2a} = \omega(L^{0^\times}) = \Gamma_{L_a} = \Gamma_{L_{2a}}$;
- when the quadratic extension L_a/L_{2a} is ramified, we have the equalities $\Gamma_{2a} = \Gamma'_{2a} = \omega(L^{0^\times}) = \omega(\varpi_{L_a}) + \Gamma_{L_{2a}}$.

2.1.13 Lemma (Summary). *Let $a \in \Phi$ be a multipliable root. If we normalize the valuation ω so that $\Gamma_{L_a} = \mathbb{Z}$, then we get:*

L_a/L_{2a}	unramified	ramified
Γ_{L_a}	\mathbb{Z}	\mathbb{Z}
$\Gamma_{L_{2a}}$	\mathbb{Z}	$2\mathbb{Z}$
Γ_a	$\frac{1}{2}\mathbb{Z}$	$\frac{1}{2}\mathbb{Z}$
Γ_{2a}	\mathbb{Z}	$1 + 2\mathbb{Z}$
Γ'_a	\mathbb{Z}	\mathbb{Z}

2.1.14 Remark. The case of a divisible root has been treated. It is the case $2a$ of a multipliable root a .

2.1.15 Remark (The case of residue characteristic 2). When the residue characteristic is any prime number (and in particular if $p = 2$), it can be seen via further investigations, that the set $L_{a,\max}^1$ is non-empty and we let $\{\delta\} = \omega(L_{a,\max}^1)$. We can compute the sets of values, depending on δ and on the ramification of L_a/L_{2a} . We get the following results:

- $\Gamma'_a = \frac{1}{2}\delta + \Gamma_{L_a}$;
- $\Gamma_a = \Gamma'_a \cup \frac{1}{2}\Gamma_{2a} = \frac{1}{2}\Gamma_{L_a}$;
- if L_a/L_{2a} is ramified, then $\Gamma'_a \cap \frac{1}{2}\Gamma_{2a} = \emptyset$ and $\Gamma_{2a} = \delta + \omega(\varpi_{L_a}) + \Gamma_{L_{2a}}$;
- if L_a/L_{2a} is unramified, then $\Gamma'_a \cap \frac{1}{2}\Gamma_{2a} \neq \emptyset$ and $\Gamma_{2a} = \Gamma_{L_{2a}} = \Gamma_{L_a}$.

Because $\delta = 0$ when $p \neq 2$, this is, in fact, the generalisation to any residue characteristic.

2.2 The reduced case

Let $a \in \Phi$ be a non-multipliable root of Φ arising from an absolute root $\alpha \in \tilde{\Phi}$. In this section, in order to simplify notation, we denote $L = L_\alpha = L_a$. Denote by $G^a = \langle U_{-a}, U_a \rangle$ the K -subgroup of G generated by U_{-a} and U_a . The universal covering $\pi : R_{L/K}(SL_{2,L}) \rightarrow G^a$ is a central K -isogeny, which allows us to compute relations between the elements of U_a , U_{-a} and T by the parametrizations x_a , x_{-a} and \tilde{a} thanks to matrix realizations in SL_2 .

We denote by $T^a = T \cap G^a$ the maximal torus of G^a and by $T^a(K)_b^+ = T(K)_b^+ \cap T^a(K)$ the maximal pro- p subgroup of $T^a(K)$. By [Loi16, 3.2.10] (because G^a is simply-connected, the torus T^a is an induced torus), we know that $\tilde{a} : 1 + \mathfrak{m}_{L_a} \rightarrow T^a(K)_b^+$ is a group isomorphism.

2.2.1 Lemma (Commutation relation $[T, U_a]$ in the reduced case).

(1) Let $t \in T(K)$. Then, for any $x \in L_\alpha$, we have

$$[x_a(x), t] = x_a((1 - \alpha(t))x)$$

(2) Normalize the valuation ω by $\Gamma_a = \Gamma_{L_a} = \mathbb{Z}$. For any $l \in \Gamma_a$, we have:

$$[T(K)_b^+, U_{a,l}] \leq U_{a,l+1}$$

and this is an equality if $p \neq 2$.

Proof. (1) By definitions, $tx_a(x)t^{-1} = x_a(\alpha(t)x)$. Hence $[x_a(x), t] = x_a(x)x_a(-\alpha(t)x) = x_a((1 - \alpha(t))x)$.

(2) Let $t \in T(K)_b^+$ and $u \in U_{a,l}$. Write $u = x_a(x)$ with $x \in L_a$ such that $\omega(x) \geq l$. Write $t = \tilde{a}(1+z)$ with $z \in \mathfrak{m}_{L_a}$ so that $\alpha(t) = (1+z)^2$. In particular, $\omega(1 - \alpha(t)) \geq 1$. Applying (1), we get $\varphi_a([t, u]) = \omega((1 - \alpha(t))x)$. Hence $\varphi_a([t, u]) \geq \omega(x) + 1 \geq l + 1$. This gives the inclusion $[T(K)_b^+, U_{a,l}] \subset U_{a,l+1}$.

Conversely, let $y \in L_\alpha$ be such that $\omega(y) \geq l + 1$. Let ϖ be a uniformizer of \mathcal{O}_{L_a} . Assume $p \neq 2$. We have $\omega(2\varpi + \varpi^2) = 1$. Set $t = \tilde{a}(1 + \varpi)$ and $x = (2\varpi + \varpi^2)^{-1}y$. Then $[t, x_a(x)] = x_a(y)$ and $t \in T(K)_b^+$. Hence $\omega(x) = \omega(y) - 1 \geq l$. \square

2.2.2 Lemma (Commutation relation $[U_{-a,l}, U_{a,l'}]$ in the reduced case).

Normalize ω by $\Gamma_a = \Gamma_{L_a} = \mathbb{Z}$. Let $l, l' \in \Gamma_a = \mathbb{Z}$ such that $l + l' \geq 1$. Then, for any $x, y \in L_\alpha$ such that $\omega(x) \geq l'$ and $\omega(y) \geq l$, we have:

$$[x_{-a}(y), x_a(x)] = x_{-a}\left(\frac{xy^2}{1+xy}\right)\tilde{a}(1+xy)x_a\left(\frac{-x^2y}{1+xy}\right)$$

In particular, $[U_{-a,l}, U_{a,l'}] \subset U_{-a,l+1}T(K)_b^+U_{a,l'+1}$.

Proof. We have $\omega(xy) = \omega(x) + \omega(y) > 0$, hence $xy \in \mathfrak{m}_{L_a}$. Thus, $1+xy \in \mathcal{O}_{L_a}^\times$ and in $\mathrm{SL}_2(L_a)$, we have:

$$\left[\begin{pmatrix} 1 & 0 \\ -y & 1 \end{pmatrix}, \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}\right] = \begin{pmatrix} 1 & 0 \\ -\frac{xy^2}{1+xy} & 1 \end{pmatrix} \begin{pmatrix} 1+xy & 0 \\ 0 & \frac{1}{1+xy} \end{pmatrix} \begin{pmatrix} 1 & \frac{-x^2y}{1+xy} \\ 0 & 1 \end{pmatrix}$$

Applying π to this equality, we get the desired equality.

We have $1+xy \in 1+\mathfrak{m}_{L_a}$, hence $\tilde{a}(1-xy) \in T(K)_b^+$. Moreover, $\omega\left(\frac{xy^2}{1+xy}\right) = \omega(x) + 2\omega(y) \geq 1 + \omega(y)$ and $\omega\left(\frac{x^2y}{1+xy}\right) = 2\omega(x) + \omega(y) \geq 1 + \omega(x)$. Hence $x_{-a}\left(\frac{xy^2}{1+xy}\right) \in U_{-a,l+1}$ and $x_a\left(\frac{-x^2y}{1+xy}\right) \in U_{a,l'+1}$. \square

2.2.3 Proposition. Assume that $p \neq 2$ and $\Gamma_a = \Gamma_{L_a} = \mathbb{Z}$. Let $l \in \mathbb{Z} = \Gamma_a$. Let H be a compact open subgroup of $G^a(K)$ containing $U_{a,l}$, $T^a(K)_b^+$ and $U_{-a,-l+1}$.

Then the group $H^p[H, H]$ contains the subgroups $U_{a,l+1}$, $U_{-a,-l+2}$ and $T^a(K)_b^+$.

Moreover, in the case of equal characteristic $\mathrm{char}(K) = p$, we have the inclusion $H^p \subset [H, H]$.

Proof. Denote by ϖ a uniformizer of L_a . We firstly show that $T^a(K)_b^+$ is contained in $H^p[H, H]$. For any $t \in 1 + \mathfrak{m}_{L_a}$, $t \neq 1$ and any $u \in L_a$, one can check the following equalities inside SL_2 :

$$\left[\begin{pmatrix} t & \frac{tu}{1-t^2} \\ 0 & \frac{1}{t} \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ -\frac{(1-t^2)^2}{t^2u} & 1 \end{pmatrix}\right] = \begin{pmatrix} t^2 & u \\ 0 & \frac{1}{t^2} \end{pmatrix} \quad (1)$$

$$\left[\begin{pmatrix} 1 & \frac{t^2-1}{t^2v} \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} \frac{1}{t} & 0 \\ -\frac{tv}{(t^2-1)} & t \end{pmatrix} \right] = \begin{pmatrix} t^2 & 0 \\ v & \frac{1}{t^2} \end{pmatrix} \quad (2)$$

We have $\omega(1+t) = \omega(2+s) = 0$ because $p \neq 2$. Hence, for any $u \in \varpi^{l+1}\mathcal{O}_{L_a}$ and for any $t-1 = s \in \varpi\mathcal{O}_{L_a}$, we have the following:

$$\begin{aligned} \omega\left(\frac{tu}{1-t^2}\right) &= \omega(t) + \omega(u) - \omega(1+t) - \omega(1-t) \\ &= \omega(u) - \omega(s) \\ \omega\left(-\frac{(1-t^2)^2}{t^2u}\right) &= 2\omega(s) - \omega(u) \end{aligned}$$

Moreover, we have:

$$\begin{pmatrix} t^2 & u \\ 0 & t^{-2} \end{pmatrix} \begin{pmatrix} t^2 & -t^{-4}u \\ 0 & t^{-2} \end{pmatrix} = \begin{pmatrix} t^4 & 0 \\ 0 & t^{-4} \end{pmatrix} \quad (3)$$

Let $t = 1 + s \in 1 + \varpi\mathcal{O}_L$. Set $u = \varpi^{l+\omega(s)}$ so that $\omega\left(\frac{tu}{1-t^2}\right) \geq l$ and $\omega\left(-\frac{(1-t^2)^2}{t^2u}\right) \geq -l+1$. Hence, $\pi\left(\begin{pmatrix} t & \frac{tu}{1-t^2} \\ 0 & \frac{1}{t} \end{pmatrix}\right) \in H$ and $\pi\left(\begin{pmatrix} 1 & 0 \\ -\frac{(1-t^2)^2}{t^2u} & 1 \end{pmatrix}\right) \in H$. Thus, according to the equation (1), we get $\pi\left(\begin{pmatrix} t^2 & u \\ 0 & t^{-2} \end{pmatrix}\right) \in [H, H]$. Similarly, substituting u by $-t^4u$, we get $\pi\left(\begin{pmatrix} t^2 & -t^{-4}u \\ 0 & t^{-2} \end{pmatrix}\right) \in [H, H]$. As a consequence, for any $t \in 1 + \varpi\mathcal{O}_L$, we have $\tilde{a}(t^4) \in [H, H]$ according to the equation (3).

Moreover, the elements $\tilde{a}(t^p)$ where $t \in 1 + \mathfrak{m}_L$ are in H^p because we assumed $H \supset T(K)_b^+$. Since 4 and p are coprime, we have $\tilde{a}(t) \in H^p[H, H]$.

In the case of equal characteristic $\text{char}(K) = p > 2$, the group homomorphism $\begin{cases} 1 + \mathfrak{m}_L & \rightarrow 1 + \mathfrak{m}_L \\ t & \mapsto t^2 \end{cases}$ is surjective. Hence $\tilde{a}(t) \in [H, H]$.

As a consequence, the elements:

$$x_a(u) = \tilde{a}(t^{-2}) \cdot \left[\tilde{a}(t)x_a\left(\frac{t^2u}{1-t^2}\right), x_{-a}\left(-\frac{(1-t^2)^2}{t^4u}\right) \right]$$

where $u \in \varpi^{l+1}\mathcal{O}_L$ and $t = 1 + \varpi^{\omega(u)}$, are in $H^p[H, H]$ (resp. in $[H, H]$ if $\text{char}(K) = p$). Hence, the group $H^p[H, H]$ (resp. $[H, H]$) contains $U_{a, l+1}$.

Similarly, it contains $U_{-a, (-l+1)+1} = U_{a, -l+2}$, using the equation (2) instead of (1).

It remains to prove that $H^p \subset [H, H]$ when $\text{char}(K) = p > 2$. Let $g \in H$ and write $g = x_{-a}(v)\tilde{a}(t)x_a(u)$. Consider the quotient morphism $\pi : H \rightarrow H/[H, H]$. Then $\pi(g^p) = \pi(g)^p = \left(\pi(x_{-a}(v))\pi(\tilde{a}(t))\pi(x_a(u))\right)^p$. Since $H/[H, H]$ is commutative, we have $\pi(g^p) = \pi(x_{-a}(v))^p\pi(\tilde{a}(t))^p\pi(x_a(u))^p = \pi(x_{-a}(pv))\pi(\tilde{a}(t^p))\pi(x_a(pu)) = \pi(\tilde{a}(t^p)) = 1$ because we got $\tilde{a}(t^p) \in [H, H]$. Hence $g^p \in [H, H]$. \square

2.3 The non-reduced case

Let $a \in \Phi$ be a multipliable root of Φ arising from an absolute root $\alpha \in \tilde{\Phi}$.

In this paragraph, we denote by $L = L_\alpha = L_a$ and $L_2 = L_{\alpha+\tau\alpha} = L_{2a}$, where $\tau = \tau_a$ is the non trivial element of $\text{Gal}(L/L_2)$. In order to simplify

notations, for any $x \in L$, we denote ${}^\tau x = \tau(x)$. Denote by h the L_2 -Hermitian form:

$$\begin{aligned} h : L \times L \times L &\rightarrow L \\ (x_{-1}, x_0, x_1) &\mapsto \sum_{i=-1}^1 x_{-i} {}^\tau x_i \end{aligned}$$

Recall that the universal covering is a central K -isogeny $\pi : R_{L/k}(SU(h)) \rightarrow G^a$, from which we compute, inside $SU(h)$, relations between elements of U_a , U_{-a} and T thanks to parametrizations x_a , x_{-a} and \tilde{a} .

Denote by $T^a = T \cap G^a$ and $T^a(K)_b^+ = T(K)_b^+ \cap T^a(K)$, so that $T^a(K)_b^+ = \tilde{a}(1 + \mathfrak{m}_{L_a})$. For any $l \in \mathbb{N}^*$, set $T^a(K)_b^l = \tilde{a}(1 + \mathfrak{m}_{L_a}^l)$. Normalize ω by $\Gamma_a = \Gamma_{-a} = \frac{1}{2}\mathbb{Z}$, so that $\Gamma_L = \mathbb{Z}$ and $\Gamma_{L_2} = 2\mathbb{Z}$ or \mathbb{Z} depending on whether the extension L/L_2 is ramified or not. The analogue to Proposition 2.2.3, in the non-reduced case, is the following:

2.3.1 Proposition. *Assume that $p \geq 5$. Let $l \in \Gamma_a = \frac{1}{2}\mathbb{Z}$. Let H be a compact open subgroup of $G(K)$ containing the following subgroups $T(K)_b^+$, $U_{-a, -l}$ and $U_{a, l + \frac{1}{2}}$.*

If L/L_2 is not ramified, then there exists $l'' \in \mathbb{N}^$ such that $H^p[H, H]$ contains the following subgroups $T^a(K)_b^{l''}$, $U_{-a, -l+1}$ and $U_{a, l + \frac{3}{2}}$.*

If L/L_2 is ramified, then there exists $l'' \in \mathbb{N}^$ such that $H^p[H, H]$ contains the following subgroups $T^a(K)_b^{l''}$, $U_{-a, -l + \frac{3}{2}}$ and $U_{a, l+2}$.*

Precisely, up to exchanging a with $-a$, we can assume $l \in \Gamma'_a = \mathbb{Z}$ and, in this case, we get $l'' = 3 + \varepsilon$ where

$$\varepsilon = \begin{cases} 1 & \text{if } L/L_2 \text{ is ramified and } l \in 2\mathbb{Z} + 1 = \Gamma_L \setminus \Gamma_{L_2} \\ 0 & \text{otherwise} \end{cases}$$

Moreover, when $\text{char}(K) = p > 0$, we have $H^p \subset [H, H]$.

2.3.2 Remark. Since the maximal pro- p subgroups are pairwise conjugated by [Loi16, 1.2.1], by the choice of a maximal pro- p subgroup corresponding to a suitable alcove, we can assume later that $\varepsilon = 0$. Such a choice will be done in Section 3.1.2. Moreover, because of the lack of rigidity, computations in the rank 1 case gives large inequalities for the commutator group. In fact, when the rank is ≥ 2 , we can make a stronger assumption, to get a more precise computation of the Frattini subgroup, as stated in Proposition 2.3.11.

In order to simplify notation, denote by $H(L, L_2)$ the rational points of the K -group $H(L, L_2)$, instead of $H(L, L_2)(K)$. For any $(x, y), (u, v) \in H(L, L_2)$ and for any $t \in 1 + \varpi_L \mathcal{O}_L$, up to precomposing by π , we have the following matrix realization:

$$\begin{aligned} \tilde{a}(t) &= \begin{pmatrix} t & 0 & 0 \\ 0 & t^{-1} {}^\tau t & 0 \\ 0 & 0 & {}^\tau t^{-1} \end{pmatrix} \\ x_a(x, y) &= \begin{pmatrix} 1 & -{}^\tau x & -y \\ 0 & 1 & x \\ 0 & 0 & 1 \end{pmatrix} & x_{-a}(u, v) &= \begin{pmatrix} 1 & 0 & 0 \\ u & 1 & 0 \\ -v & -{}^\tau u & 1 \end{pmatrix} \end{aligned}$$

We want to obtain some unipotent elements, and some semisimple elements, by multiplying suitable commutators and p -powers of elements in H , as we have done, previously, in the reduced case. In particular, in Lemma 2.3.4 we bound explicitly, thanks to these parametrizations, the group generated by commutators of toric elements and unipotent elements in a given root group.

In Lemma 2.3.6, we provide an explicit formula for the commutators of unipotent elements taken in opposite root groups, in terms of the parametrizations. Finally, thanks to Lemma 2.3.10, we invert such a commutation relation. At last, we prove Proposition 2.3.1 thanks to these lemmas.

The following lemma provides the existence of elements with minimal valuation, used in the parametrization of coroots.

2.3.3 Lemma. *Let L/K be a quadratic Galois extension of local fields and $\tau \in \text{Gal}(L/K)$ be the non-trivial element. Let ϖ_L be a uniformizer of the local ring \mathcal{O}_L . Denote by p the residue characteristic and assume that $p \neq 2$.*

- (1) *For any $\forall t \in 1 + \mathfrak{m}_L$, we have $\omega(t^2 - {}^\tau t) \geq \omega(\varpi_L)$ and $\omega(t^\tau t - 1) \geq \omega(\varpi_L)$.*
- (2) *If the extension L/K is unramified, then there exists $t \in 1 + \mathfrak{m}_L$ such that $\omega(t^\tau t - 1) = \omega(t^2 - {}^\tau t) = \omega(\varpi_L)$.*
- (3) *If the extension L/K is ramified, then for any $t \in 1 + \mathfrak{m}_L$, we have the inequality $\omega(t^\tau t - 1) \geq 2\omega(\varpi_L)$. If $p \geq 5$, then there exists $t \in 1 + \mathfrak{m}_L$ such that $\omega(t^\tau t - 1) = 2\omega(t^2 - {}^\tau t) = 2\omega(\varpi_L)$.*

Proof. (1) Write $t = 1 + s$ with $\omega(s) \geq \omega(\varpi_L)$. Then $\omega(t^2 - {}^\tau t) = \omega(2s + s^2 - {}^\tau s) \geq \omega(s)$ and $\omega(t^\tau t - 1) = \omega(s + {}^\tau s + s^\tau s) \geq \omega(s)$.

(2) If L/K is unramified, one can choose a uniformizer $\varpi_L \in \mathcal{O}_L \cap K$. Let $t = 1 + \varpi_L$, so that $t^2 - {}^\tau t = \varpi_L + \varpi_L^2$. Since $p \neq 2$, then $\omega(2) = 0$. Hence $\omega(t^\tau t - 1) = \omega(2\varpi_L + \varpi_L^2) = \omega(\varpi_L)$.

(3) If L/K is ramified, the inequality $\omega(t^\tau t - 1) \geq \omega(\varpi_L)$ is never an equality because $t^\tau t - 1 \in K$. Consequently, $\omega(t^\tau t - 1) \geq 2\omega(\varpi_L)$. Remark that $\omega(\varpi_L + {}^\tau \varpi_L) \geq 2\omega(\varpi_L) = \omega(\varpi_L {}^\tau \varpi_L)$. Define $t = 1 + \varpi_L$, so that $t^2 - {}^\tau t = 2\varpi_L - {}^\tau \varpi_L + \varpi_L^2$.

By contradiction, if we had $\omega(2\varpi_L - {}^\tau \varpi_L) \geq 2\omega(\varpi_L)$, then, by triangle inequality, we would get $\omega(3\varpi_L) \geq \min(\omega(\varpi_L + {}^\tau \varpi_L), \omega(2\varpi_L - {}^\tau \varpi_L)) \geq 2\omega(\varpi_L)$. When $p \neq 3$, we have $\omega(3\varpi_L) = \omega(\varpi_L)$. Hence, there is a contradiction with $\omega(\varpi_L) > 0$. As a consequence, $\omega(2\varpi_L - {}^\tau \varpi_L) = \omega(\varpi_L)$, for any uniformizer $\varpi_L \in \mathcal{O}_L$.

Define $\varpi'_L = \varpi_L + \varpi_L {}^\tau \varpi_L$. This element $\varpi'_L \in \mathcal{O}_L$ is also a uniformizer. Define $t' = 1 + \varpi'_L$. We have seen that $\omega(t'^2 - {}^\tau t') = \omega(\varpi_L)$.

Claim: Either t or t' satisfies the desired equalities.

Indeed, we have $t^\tau t - 1 = \varpi_L + {}^\tau \varpi_L + \varpi_L {}^\tau \varpi_L$ and $t'^\tau t' - 1 = \varpi_L + {}^\tau \varpi_L + 3\varpi_L {}^\tau \varpi_L + \text{Tr}_{L/K}(\varpi_L^2 {}^\tau \varpi_L) + N_{L/K}(\varpi_L)^2$.

By contradiction, assume that we have $\omega(\varpi_L + {}^\tau \varpi_L + \varpi_L {}^\tau \varpi_L) > 2\omega(\varpi_L)$ and $\omega(\varpi_L + {}^\tau \varpi_L + 3\varpi_L {}^\tau \varpi_L) > 2\omega(\varpi_L)$. Then, by triangle inequality, we get $\omega(2\varpi_L {}^\tau \varpi_L) > 2\omega(\varpi_L)$. Since $p \neq 2$, we have $\omega(2\varpi_L {}^\tau \varpi_L) = 2\omega(\varpi_L)$ and there is a contradiction.

Hence, we have, at least, $\omega(\varpi_L + {}^\tau \varpi_L + \varpi_L {}^\tau \varpi_L) = 2\omega(\varpi_L)$, or $\omega(\varpi_L + {}^\tau \varpi_L + 3\varpi_L {}^\tau \varpi_L) = 2\omega(\varpi_L)$. So, at least one of the two following equalities $\omega(t^\tau t - 1) = 2\omega(\varpi_L)$ or $\omega(t'^\tau t' - 1) = 2\omega(\varpi_L)$ is satisfied. Hence t or t' is suitable. \square

Denote by $H(L, L_2)_l = \{(u, v) \in H(L, L_2), \frac{1}{2}\omega(v) \geq l\}$ the filtered subgroup of $H(L, L_2)$. Remark that $H(L, L_2)_l$ can be seen as the integral points of a \mathcal{O}_K -model of the K -group scheme $H(L, L_2)$, namely the group scheme \mathcal{H}^l defined by [Lan96, 4.23]. Recall that for any $l \in \mathbb{R}$, we have $H(L, L_2)_l \simeq U_{a,l}$, by definition of the filtration on root groups, through the

isomorphism $(u, v) \mapsto x_a(u, v)$. Recall that we also have an isomorphism $\tilde{a} : 1 + \mathfrak{m}_L \simeq T^a(K)_b^+$.

2.3.4 Lemma. *Let $l \in \Gamma_a = \frac{1}{2}\mathbb{Z}$.*

If L/L_2 is unramified, we have

$$U_{a,l+1} \subset [T(K)_b^+, U_{a,l}] \subset U_{a,l+\frac{1}{2}}$$

If L/L_2 is ramified, we have

$$U_{a,l+\frac{3}{2}} \subset [T(K)_b^+, U_{a,l}] \subset U_{a,l+\frac{1}{2}}$$

Proof. For any $t \in 1 + \varpi_L \mathcal{O}_L \simeq T(K)_b^+$ and all $(u, v) \in H(L, L_2)_l$, we have:

$$\left[\begin{pmatrix} 1 & -\tau u & -v \\ 0 & 1 & u \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} t & 0 & 0 \\ 0 & \frac{\tau t}{t} & 0 \\ 0 & 0 & \frac{1}{\tau t} \end{pmatrix} \right] = \begin{pmatrix} 1 & -\tau U & -V \\ 0 & 1 & U \\ 0 & 0 & 1 \end{pmatrix}$$

where $U = \left(1 - \frac{\tau t^2}{t}\right)u$ and $V = \left(1 - \frac{\tau t^2}{t}\right)v + \left(t^\tau t - \frac{\tau t^2}{t}\right)\tau v$. One can check that $(U, V) \in H(L, L_2)$. We have:

$$\begin{aligned} \omega(V) &\geq \min \left(\omega(t - \tau t^2) + \omega(v) - \omega(t), \omega\left(\frac{\tau t}{t}\right) + \omega(t^2 - \tau t) + \omega(\tau v) \right) \\ &\quad \text{by the triangle inequality} \\ &= \omega(v) + \omega(t^2 - \tau t) \quad \text{because } \tau \text{ preserves the valuation} \\ &\geq 2l + 1 \quad \text{by lemma 2.3.3(1)} \end{aligned}$$

From this inequality, we deduce $(U, V) \in H(L, L_2)_{l+\frac{1}{2}}$, hence we have $[U_{a,l}, T(K)_b^+] \subset U_{a,l+\frac{1}{2}}$.

Conversely, let $l' \in \frac{1}{2}\mathbb{Z}$. Let $(U, V) \in H(L, L_2)_{l'}$. We want elements $t \in 1 + \mathfrak{m}_L$ and $(u, v) \in H(L, L_2)$ such that $[\tilde{a}(t), x_a(u, v)] = x_a(U, V)$ and so that $\omega(v)$ is as big as possible.

Choose t satisfying the equalities (2) or (3) in Lemma 2.3.3 applied to the extension of local fields L/L_2 . Let $u = \frac{t}{t - \tau t^2}U$. We seek $X, Y \in \mathcal{O}_K(t, \tau t)$ such that $\left(1 - \frac{\tau t^2}{t}\right)v + \left(t^\tau t - \frac{\tau t^2}{t}\right)\tau v = V$ where we set $v = XV + Y^\tau V$. It suffices to find X, Y such that:

$$\begin{cases} \left(1 - \frac{\tau t^2}{t}\right)X + \left(t^\tau t - \frac{\tau t^2}{t}\right)\tau Y &= 1 \\ \left(1 - \frac{\tau t^2}{t}\right)Y + \left(t^\tau t - \frac{\tau t^2}{t}\right)\tau X &= 0 \end{cases}$$

The unique solution of this linear system is:

$$\begin{cases} X &= \frac{1}{(1 - t^\tau t)\left(1 - \frac{\tau t^2}{t}\right)} \\ Y &= \frac{\frac{\tau t^2}{t}}{(1 - t^\tau t)\left(1 - \frac{\tau t^2}{t}\right)} \end{cases}$$

so that:

$$v = XV + Y^\tau V = \frac{V + \frac{\tau t^2}{t}\tau V}{(1 - t^\tau t)\left(1 - \frac{\tau t^2}{t}\right)}$$

satisfies $(u, v) \in H(L, L_2)$.

By a matrix computation, and because t, u, v have been chosen for this, we can check that $[x_a(u, v), \tilde{a}(t)] = x_a(U, V)$. Moreover, the valuation gives us $\omega(v) \geq \omega(V) - \omega(1 - t^\tau t) - \omega(t - \tau t^2)$ because $\omega\left(V + \frac{\tau t^2}{t}\tau V\right) \geq \omega(V)$.

When L/L_2 is unramified, by 2.3.3(2), this gives us $\omega(v) \geq 2l' - 2$. From this inequality, we deduce $(u, v) \in H(L, L_2)_{l'-1}$, hence:

$$[U_{a, l'-1}, T(K)_b^+] \supset U_{a, l'}$$

When L/L_2 is ramified, by 2.3.3(3), this gives us $\omega(v) \geq 2l' - 3$. From this inequality, we deduce $(u, v) \in H(L, L_2)_{l'-\frac{3}{2}}$, hence:

$$[U_{a, l'-\frac{3}{2}}, T(K)_b^+] \supset U_{a, l'}$$

□

2.3.5 Remark. These inequalities could be refined, with a deeper study on the arithmetic properties of the local fields. As an example, when L/L_2 is ramified, and $l \notin \mathbb{Z}$, we obtain $[T(K)_b^+, U_{a, l}] \subset U_{a, l+1}$.

2.3.6 Lemma (Commutation of opposite root groups). *Let $l, l' \in \Gamma_a = \frac{1}{2}\Gamma_L = \frac{1}{2}\mathbb{Z}$ be such that $l + l' > 0$. Let $(x, y) \in H(L, L_2)_l$ and $(u, v) \in H(L, L_2)_{l'}$. We have $[x_{-a}(x, y), x_a(u, v)] = x_{-a}(X, Y)\tilde{a}(T)x_a(U, V)$ where:*

$$\begin{cases} T &= 1 - {}^\tau ux + vy \\ U &= \frac{1}{{}^\tau T} (u^2 {}^\tau x - {}^\tau vx - u {}^\tau v {}^\tau y) \\ V &= \frac{1}{T} (uv {}^\tau x - {}^\tau u {}^\tau vx + v {}^\tau vy) \\ X &= \frac{1}{T} ({}^\tau ux^2 - uy + vxy) \\ Y &= \frac{1}{T} ({}^\tau xuy - {}^\tau ux {}^\tau y + v {}^\tau y) \end{cases}$$

Moreover, $\omega(V) \geq \lceil 3l' + l \rceil$ and $\omega(Y) \geq \lceil l' + 3l \rceil$.

Consequently,

$$\begin{aligned} [U_{-a, l}, U_{a, l'}] &\subset U_{-a, \lceil \frac{3l+l'}{2} \rceil} T^a(K)_b^+ U_{a, \lceil \frac{l+3l'}{2} \rceil} \\ &\subset U_{-a, l+\frac{1}{2}} T^a(K)_b^+ U_{a, l'+\frac{1}{2}} \end{aligned}$$

Proof. Because τ preserves ω , we have the following in $H(L, L_2)$:

$$2\omega(u) = \omega(u {}^\tau u) = \omega(v + {}^\tau v) \geq \omega(v)$$

Hence, we have:

$$\omega(x) + \omega(u) \geq \frac{1}{2}(\omega(y) + \omega(v)) \geq l + l' > 0$$

By a matrix computation in $SU(h)$, we have:

$$\begin{pmatrix} 1 & -{}^\tau u & -v \\ 0 & 1 & u \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ x & 1 & 0 \\ -y & -{}^\tau x & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ X_0 & 1 & 0 \\ -Y_0 & -{}^\tau X_0 & 1 \end{pmatrix} \begin{pmatrix} T & 0 & 0 \\ 0 & \frac{{}^\tau T}{T} & 0 \\ 0 & 0 & \frac{1}{{}^\tau T} \end{pmatrix} \begin{pmatrix} 1 & -{}^\tau U_0 & -V_0 \\ 0 & 1 & U_0 \\ 0 & 0 & 1 \end{pmatrix}$$

where

$$\begin{cases} T &= 1 - {}^\tau ux + vy \\ U_0 &= \frac{1}{{}^\tau T} (u - {}^\tau vx) \\ V_0 &= \frac{1}{T} v \\ X_0 &= \frac{1}{T} (x - uy) \\ Y_0 &= \frac{1}{T} y \end{cases}$$

Because $\omega({}^\tau ux) \geq \frac{1}{2}\omega(vy) > 0$, we get $T \in 1 + \mathfrak{m}_L$. Hence $\frac{1}{T} \in \mathcal{O}_L^\times$ is well-defined. It follows:

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ -x & 1 & 0 \\ -{}^\tau y & {}^\tau x & 1 \end{pmatrix}, \begin{pmatrix} 1 & -{}^\tau u & -v \\ 0 & 1 & u \\ 0 & 0 & 1 \end{pmatrix} \right] = \begin{pmatrix} 1 & 0 & 0 \\ X & 1 & 0 \\ -Y & -{}^\tau X & 1 \end{pmatrix} \begin{pmatrix} T & 0 & 0 \\ 0 & \frac{{}^\tau T}{T} & 0 \\ 0 & 0 & \frac{1}{{}^\tau T} \end{pmatrix} \begin{pmatrix} 1 & -{}^\tau U & -V \\ 0 & 1 & U \\ 0 & 0 & 1 \end{pmatrix}$$

where

$$\begin{cases} T &= 1 - {}^\tau ux + vy \\ U &= \frac{1}{{}^\tau T} (u^{2{}^\tau} x - {}^\tau vx - u{}^\tau v{}^\tau y) \\ V &= \frac{1}{T} (uv{}^\tau x - {}^\tau u{}^\tau vx + v{}^\tau vy) \\ X &= \frac{1}{T} ({}^\tau ux^2 - uy + vxy) \\ Y &= \frac{1}{T} ({}^\tau xuy - {}^\tau ux{}^\tau y + v{}^\tau y) \end{cases}$$

We have

$$\begin{aligned} \omega(V) &\geq \min(\omega(uv{}^\tau x), \omega({}^\tau u{}^\tau vx), \omega(v{}^\tau vy)) \\ &\geq \omega(v) + \min(\omega(u) + \omega(x), \omega(v) + \omega(y)) \\ &\geq 2l' + l + l' \end{aligned}$$

Because $\omega(V) \in \mathbb{Z}$, we have in fact $\omega(V) \geq \lceil 3l' + l \rceil \geq 2l' + 1$.

We proceed in the same way to find a lower bound of $\omega(Y)$. \square

In order to compute a derived group in terms of root groups, we would like to invert the above equations. Precisely, given a $t \in 1 + \mathfrak{m}_L^{l''}$, we seek elements $(u, v), (x, y) \in H(L, L_2)$ with prescribed valuations $l, l' \in \frac{1}{2}\mathbb{Z}$ such that $t = 1 - {}^\tau ux + vy$. The existence of such $(u, v), (x, y)$ is not guaranteed if l'' is not large enough. Firstly, we seek an element $(u, v) \in H(L, L_2)_l$ such that $\omega(\text{Tr}(u))$ is minimal.

2.3.7 Lemma. *Let L/K be a quadratic Galois extension of local fields with a residue characteristic $p \neq 2$ and a discrete valuation $\omega : L^\times \rightarrow \mathbb{Z}$. There exists a uniformizer ϖ_L in \mathcal{O}_L such that $\text{Tr}_{L/K}(\varpi_L)$ is a uniformizer of \mathcal{O}_K .*

Proof. If L/K is unramified, we can choose a uniformizer ϖ_L of \mathcal{O}_L in \mathcal{O}_K . Because $p \neq 2$, the element $\text{Tr}_{L/K}(\varpi_L) = 2\varpi_L$ is a uniformizer in \mathcal{O}_K .

If L/K is ramified, let ϖ' be a uniformizer of \mathcal{O}_L . We know that $\omega(\text{Tr}_{L/K}(\varpi')) \geq \min(\omega(\varpi'), \omega({}^\tau \varpi')) = 1$. This is never an equality because $\Gamma_K = \omega(K^\times) = 2\mathbb{Z}$.

If $\omega(\text{Tr}_{L/K}(\varpi')) = 2$, then we set $\varpi_L = \varpi'$. Otherwise, we set $\varpi_L = \varpi' + N_{L/K}(\varpi')$. Thus, ϖ_L is a uniformizer because $\omega(N_{L/K}(\varpi')) = 2 > 1 = \omega(\varpi')$. Moreover, $\text{Tr}_{L/K}(\varpi_L) = \text{Tr}_{L/K}(\varpi') + 2N_{L/K}(\varpi')$. Because $\omega(\text{Tr}_{L/K}(\varpi')) > \omega(2N_{L/K}(\varpi')) = 2$, we get the result. \square

2.3.8 Lemma. *Assume that $p \neq 2$ and let $l \in \Gamma_L = \mathbb{Z}$.*

If L/L_2 is unramified, set $\varepsilon = 0$.

If L/L_2 is ramified, set $\varepsilon = \begin{cases} 0 & \text{if } l \in \Gamma_{L_2} = 2\mathbb{Z} \\ 1 & \text{otherwise} \end{cases}$

There exists $u \in L$ such that:

- (a) $\omega(u) = l$;
- (b) $\omega(\text{Tr}_{L/L_2}(u)) = l + \varepsilon$;
- (c) $(u, \frac{1}{2}u{}^\tau u) \in H(L, L_2)_l$.

Proof. Let ϖ_L be a uniformizer of \mathcal{O}_L such that $\varpi_{L_2} = \text{Tr}_{L/L_2}(\varpi_L)$ is a uniformizer of \mathcal{O}_{L_2} , such a uniformizer exists by Lemma 2.3.7. Define $u = (\varpi_L)^\varepsilon \cdot (\varpi_{L_2})^{\frac{l-\varepsilon}{\omega(\varpi_{L_2})}}$.

$$(a) \quad \omega(u) = \varepsilon\omega(\varpi_L) + \frac{l-\varepsilon}{\omega(\varpi_{L_2})}\omega(\varpi_{L_2}) = l.$$

(b) We have:

$$\begin{aligned} \text{Tr}_{L/L_2}(u) &= \text{Tr}_{L/L_2}((\varpi_L)^\varepsilon) \cdot (\varpi_{L_2})^{\frac{l-\varepsilon}{\omega(\varpi_{L_2})}} \\ &= \begin{cases} (\varpi_{L_2})^{\frac{l-\varepsilon}{\omega(\varpi_{L_2})} + \varepsilon} & \text{if } \varepsilon = 1 \\ 2(\varpi_{L_2})^{\frac{l-\varepsilon}{\omega(\varpi_{L_2})}} & \text{if } \varepsilon = 0 \end{cases} \end{aligned}$$

$$\text{Hence } \omega(\text{Tr}_{L/L_2}(u)) = \left(\frac{l-\varepsilon}{\omega(\varpi_{L_2})} + \varepsilon\right)\omega(\varpi_{L_2}) = l - \varepsilon + \varepsilon\omega(\varpi_{L_2}) = l + \varepsilon.$$

$$(c) \quad \text{We have } N_{L/L_2}(u) = u^\tau u = \text{Tr}\left(\frac{1}{2}u^\tau u\right). \quad \square$$

As a consequence, we got an element (u, v) such that $\text{Tr}_{L/L_2}(u)$ is minimal. Secondly, we seek an element $(x, y) \in H(L, L_2)_{l'}$ such that $t = 1 - {}^\tau ux + vy$. This is a quadratic problem. That is why we recall the following lemma on the existence of square root.

2.3.9 Lemma. *Let L be a local field of residue characteristic $p \neq 2$. For all $a \in \mathfrak{m}_L$, there exists $b \in \mathfrak{m}_L$ such that $(1+b)^2 = 1+a$ and $\omega(a) = \omega(b)$.*

Proof. Let $a \in \mathfrak{m}_L$. By Hensel's Lemma, the polynomial $X^2 - 1 - a$ admits exactly two roots $1+b$ and $-1+b'$ in \mathcal{O}_L , with $b, b' \in \mathfrak{m}_L$ since 1 and -1 are two distinct roots in κ_L of the polynomial $X^2 - 1$. Moreover $\omega(a) = \omega((1+b)^2 - 1) = \omega(b) + \omega(2+b)$. Since $p \neq 2$, we have $\omega(2+b) = 0$. Hence, $\omega(a) = \omega(b)$. \square

We provide a solution $(x, y) \in H(L, L_2)_{l'}$ of $t = 1 - {}^\tau ux + vy$ for a suitable value l'' such that $t \in 1 + \mathfrak{m}_L^{l''}$.

2.3.10 Lemma. *Assume that $p \neq 2$. Let $l, l' \in \Gamma_a$ be such that $l + l' > 0$ and $l \in \Gamma'_a = \mathbb{Z}$. Define $\varepsilon \in \{0, 1\}$ as in Lemma 2.3.8. Define*

$$l'' = \max(1 + 2\varepsilon, \varepsilon + 2l + 2l') \in \mathbb{N}^*$$

For any $w \in \mathfrak{m}_L^{l''}$, there exist $(u, v) \in H(L, L_2)_l$ and $(x, y) \in H(L, L_2)_{l'}$ such that ${}^\tau ux - vy = w$.

Proof. In order to simplify notation in this proof, we denote by T the field trace operator $\text{Tr}_{L/L_2} : L \rightarrow L_2$.

Let $w \in (\mathfrak{m}_L)^{l''}$. Choose $u \in L$ satisfying the properties (a), (b) and (c) of Lemma 2.3.8 and set $v = \frac{1}{2}u^\tau u$. We seek an element $(x, y) \in H(L, L_2) \cap (L_2 \times L)$ such that ${}^\tau xu - vy = w$, which is equivalent to

$$\begin{cases} y = \frac{-w + {}^\tau ux}{v} \\ x^2 = T(y) = -T\left(\frac{w}{v}\right) + xT\left(\frac{{}^\tau u}{v}\right) \end{cases}$$

because $v \neq 0$ (otherwise property (a) would be contradicted).

Denote $\delta = 4 \frac{T(\frac{w}{v})}{T(\frac{{}^\tau u}{v})^2}$. We have $T\left(\frac{{}^\tau u}{v}\right) = 2 \frac{T(u)}{u^\tau u}$ by definition of $v = \frac{1}{2}u^\tau u \in L_2$ and by L_2 -linearity of T . Hence $\omega\left(T\left(\frac{{}^\tau u}{v}\right)\right) = \omega(T(u)) - 2\omega(u) = -l + \varepsilon$. We have $\omega\left(T\left(\frac{w}{v}\right)\right) \geq \omega(w) - \omega(v) \geq l'' - 2l$. Hence $\omega(\delta) = \omega\left(T\left(\frac{w}{v}\right)\right) - 2\omega\left(T\left(\frac{{}^\tau u}{v}\right)\right) \geq l'' - 2\varepsilon \geq 1$. By Lemma 2.3.9, there exists $b \in \mathfrak{m}_{L_2}$ such

that $(1+b)^2 = 1 - \delta$ and $\omega(b) = \omega(\delta)$. We denote $\sqrt[2]{1-\delta} = 1+b$. Hence $\sqrt[2]{1-\delta} \in 1 + \delta\mathcal{O}_{L_2}$ is well-defined and $\omega(\sqrt[2]{1-\delta} - 1) = \omega(\delta)$.

Set $x = \frac{1}{2}T\left(\frac{\tau u}{v}\right)(1 - \sqrt[2]{1-\delta}) \in L_2$ and set $y = \frac{w - \tau ux}{v} \in L$. We have $x^2 = T(y)$. Moreover, $\omega(x) = \omega(\delta) + \varepsilon - l$. We check the valuation of y :

$$\begin{aligned} \omega(y) &\geq \min(\omega(w), \omega(u) + \omega(x)) - \omega(v) \\ &= \min(l'', \omega(\delta) + \varepsilon) - 2l \\ &\geq \min(l'', l'' - 2\varepsilon + \varepsilon) - 2l \\ &= l'' - \varepsilon - 2l \\ &\geq 2l' \end{aligned}$$

Hence $(u, v) \in H(L, L_2)_l$ and $(x, y) \in H(L, L_2)_{l'}$ are suitable. \square

Finally, we can combine Lemmas 2.3.4, 2.3.6 and 2.3.10 in order to prove Proposition 2.3.1.

Proof of Proposition 2.3.1. Up to exchanging a and $-a$, one can suppose $l \in \Gamma'_a = \mathbb{Z} = \Gamma_L$.

By Lemma 2.3.4, we get $U_{-a, -l+1} \subset [H, H]$ and $U_{a, l+\frac{3}{2}} \subset [H, H]$ when L/L_2 is unramified; we get $U_{-a, -l+\frac{3}{2}} \subset [H, H]$ and $U_{a, l+2} \subset [H, H]$ when L/L_2 is ramified.

Let $t \in T^a(K)_b^{l''}$ and write it $t = \tilde{a}(1+w)$ where $w \in (\mathfrak{m}_L)^{l''}$. Set $l_0 = l+1 \in \mathbb{Z}$ et $l'_0 = -l + \frac{1}{2}$. By Lemma 2.3.10, there exists $(u, v) \in H(L, L_2)_{l_0}$ and $(x, y) \in H(L, L_2)_{l'_0}$ such that $-w = {}^\tau ux - vy$.

We use the commutation relation of opposite root groups 2.3.6. Let:

$$\begin{cases} T &= 1+w \\ U &= \frac{1}{\tau T} (u^{2\tau}x - {}^\tau vx - u^\tau v^\tau y) \\ V &= \frac{1}{T} (uv^\tau x - {}^\tau u^\tau vx + v^\tau vy) \\ X &= \frac{1}{T} ({}^\tau ux^2 - uy + vxy) \\ Y &= \frac{1}{T} ({}^\tau xuy - {}^\tau ux^\tau y + vy^\tau y) \end{cases}$$

By Lemma 2.3.6, we have $[x_{-a}(x, y), x_a(u, v)] = x_{-a}(X, Y)\tilde{a}(T)x_a(U, V)$ with $\omega(V) \geq \lceil 3l' + l \rceil$ and $\omega(Y) \geq \lceil l' + 3l \rceil$.

Because $l \in \mathbb{Z}$, we have $\frac{1}{2}\lceil 3l'_0 + l_0 \rceil = -l + \frac{3}{2}$ and $\frac{1}{2}\lceil l'_0 + 3l_0 \rceil = l+2$. Hence $x_{-a}(X, Y) \in [T(K)_b^+, U_{-a, l}]$ and $x_a(U, V) \in [T(K)_b^+, U_{a, l+\frac{1}{2}}]$ by Lemma 2.3.4. Because $\tilde{a}(1+w) = x_{-a}(X, Y)^{-1} [x_{-a}(x, y), x_a(u, v)] x_a(U, V)^{-1} \in [H, H]$, we get $T^a(K)_b^{l''} \subset [H, H]$.

We now assume that $\text{char}(K) = p \geq 5$. It suffices to check that $H^p \subset [H, H]$. Inside $H/[H, H]$, we have $u^p = 1$ for any $u \in U_{a, l}$ and it is the same for $-a$. Indeed, the element $x_a(u, v)^p = x_a\left(pu, pv + \frac{p(p-1)}{2}u^\tau u\right)$ is the neutral element in characteristic $p \neq 2$.

Moreover, if $t \in T^a(K)_b^+$, write $t = \tilde{a}(1+w)$ where $w \in \mathfrak{m}_L$. We have $(1+w)^p = 1+w^p$ with $\omega(w^p) \geq p \geq 5 \geq l''$. Hence $t^p \in T^a(K)_b^{l''} \subset [H, H]$. \square

In the case of higher rank, we obtain in Proposition 4.1.3 some inclusions of the form $U_{a, l_a} \subset [H, H]$ with a suitable value l_a , by commuting some root groups corresponding to non-collinear roots. Hence, it is useful to do a further assumption on subgroups contained in $[H, H]$.

2.3.11 Proposition. *If in Proposition 2.3.1 we furthermore assume that $[H, H]H^p$ contains $U_{a, l+1}$ and $U_{-a, -l+\frac{1}{2}}$, then one can take $l'' = 1 + 2\varepsilon$.*

Proof. In the above proof, up to exchanging a and $-a$ so that $l \in \mathbb{Z} + \frac{1}{2}$ and $l' \in \mathbb{Z}$, we can replace the equalities $l_0 = l + 1$ and $l'_0 = -l + \frac{1}{2}$ by $l_0 = l + \frac{1}{2} \in \mathbb{Z}$ and $l'_0 = -l$. Indeed, in this case we obtain $\lceil 3l'_0 + l_0 \rceil = \lceil -2l + \frac{1}{2} \rceil = -2l + 1$, so that $U_{-a, \frac{1}{2}\lceil 3l'_0 + l_0 \rceil} \subset H^p[H, H]$ by the additional assumption. In the same way, $\lceil 3l'_0 + l_0 \rceil = 2l + 2$ so that $U_{a, \frac{1}{2}\lceil l'_0 + 3l_0 \rceil} \subset H^p[H, H]$. As a consequence, we can conclude as before. \square

To conclude this section, we compute the commutation relation between elements of the same root group. This is non-trivial because, in the non-reduced case, the root group is non-commutative. This will be useful in order to understand the action of a maximal pro- p subgroup on the Bruhat-Tits building.

2.3.12 Lemma (Computation of the derived group of a valued root group: specificity on the non-reduced case). *Let $l, l' \in \Gamma_a = \frac{1}{2}\mathbb{Z}$. In general, we have $[U_{a,l}, U_{a,l'}] \subset U_{2a, \lceil l \rceil + \lceil l' \rceil}$.*

If L/L_2 is unramified and $p \neq 2$, then $[U_{a,l}, U_{a,l}] = U_{2a, 2\lceil l \rceil}$.

If L/L_2 is ramified and $p \neq 2$, then $[U_{a,l}, U_{a,l}] = U_{2a, 2\lceil l \rceil + 1}$.

Proof. Let $(u, v), (x, y) \in H(L, L_2)$. In matrix-wise terms, we have

$$\left[\begin{pmatrix} 1 & -\tau x & -y \\ 0 & 1 & -x \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & -\tau u & -v \\ 0 & 1 & -u \\ 0 & 0 & 1 \end{pmatrix} \right] = \begin{pmatrix} 1 & 0 & x^\tau u - u^\tau x \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We deduce that $[x_a(x, y), x_a(u, v)] = x_a(0, x^\tau u - u^\tau x)$.

If $\omega(y) \geq 2l$, then $\omega(x) \geq \lceil l \rceil$ because $\omega(x) \in \Gamma_L = \mathbb{Z}$. Likewise, if $\omega(v) \geq 2l'$, then $\omega(u) \geq \lceil l' \rceil$. Hence $\omega(x^\tau u - u^\tau x) \geq \omega(u) + \omega(x) \geq \lceil l \rceil + \lceil l' \rceil$. We obtain $[U_{a,l}, U_{a,l}] \subset U_{2a, \lceil l \rceil + \lceil l' \rceil}$.

Conversely, we show that any element of $U_{2a, 2\lceil l \rceil}$ can be written as the commutator of two suitable elements in $U_{a,l}$. For that, it suffices to show that for any $w \in (L^0)_{2\lceil l \rceil}$, there exist $(u, v), (x, y) \in H(L, L_2)_l$ such that $w = x^\tau u - u^\tau x$.

We firstly consider the case of a unramified extension L/L_2 with $p \neq 2$. In this case, we have $\Gamma'_{2a} = \Gamma_{2a} = \mathbb{Z}$ by Lemma 2.1.13. Hence, there exists $\lambda_0 \in (L^0)_0 = \{\lambda \in \mathcal{O}_L^\times, \lambda + {}^\tau \lambda = 0\}$. Let $\varpi \in \mathcal{O}_{L_2}$ be a uniformizer. Set $x = \lambda_0 \varpi^{\lceil l \rceil}$ and set $y = \frac{1}{2} x^\tau x$ so that $(x, y) \in H(L, L_2)_l$. Let $w \in (L^0)_{2\lceil l \rceil} = \{w_0 \in (\mathfrak{m}_L)^{2\lceil l \rceil}, w_0 + {}^\tau w_0 = 0\}$. Then $u = \frac{w}{x - {}^\tau x} \in L_2$. Indeed, ${}^\tau u = \frac{{}^\tau w}{{}^\tau x - x} = \frac{-w}{-(x - {}^\tau x)} = u$. Moreover, $\omega(x - {}^\tau x) = \omega((\lambda_0 - {}^\tau \lambda_0) \varpi^{\lceil l \rceil}) = \omega(2\lambda_0) + \omega(\varpi^{\lceil l \rceil}) = \lceil l \rceil$ because $p \neq 2$. Hence $\omega(u) = \omega(w) - \omega(x - {}^\tau x) = \lceil l \rceil$. Set $v = \frac{1}{2} u^\tau u = \frac{u^2}{2}$ so that $(u, v) \in H(L, L_2)_l$. We have $x^\tau u - u^\tau x = u(x - {}^\tau x) = w$.

We secondly consider the case of a ramified extension L/L_2 with $p \neq 2$. In this case, $\Gamma'_{2a} = \Gamma_{2a} = 2\mathbb{Z} + 1$ by Lemma 2.1.13. Thus $U_{2a, 2\lceil l \rceil} = U_{2a, 2\lceil l \rceil + 1}$. Moreover, there exists $\lambda_0 \in (L^0)_1 = \{\lambda \in \mathcal{O}_L, \lambda + {}^\tau \lambda = 0 \text{ et } \omega(\lambda) = 1\}$. Let $\varpi \in \mathcal{O}_{L_2}$ be a uniformizer.

If $\lceil l \rceil \in 2\mathbb{Z}$, we set $x = \lambda_0 \varpi^{\frac{\lceil l \rceil}{2}}$ and $y = \frac{1}{2} x^\tau x$ so that $(x, y) \in H(L, L_2)_l$.

Otherwise, $\lceil l \rceil \in 2\mathbb{Z} + 1$. We set $x = \lambda_0 \varpi^{\frac{\lceil l \rceil - 1}{2}}$ and $y = \frac{1}{2} x^\tau x$ so that $(x, y) \in H(L, L_2)_l$.

Let $w \in (L^0)_{2\lceil l \rceil} = \{w_0 \in (\mathfrak{m}_L)^{2\lceil l \rceil}, w_0 + {}^\tau w_0 = 0\}$. Then, as before, we get $u = \frac{w}{x - {}^\tau x} \in L_2$. Moreover, $\omega((\lambda_0 - {}^\tau \lambda_0) \varpi^{\frac{\lceil l \rceil - 1}{2}}) = \omega(2\lambda_0) = 1$ because $p \neq 2$. Hence, we obtain the inequalities $\omega(x) \geq \lceil l \rceil$ and $\omega(x - {}^\tau x) \leq \lceil l \rceil + 1$. Hence $\omega(u) = \omega(w) - \omega(x - {}^\tau x) \geq \lceil l \rceil$. We set $v = \frac{1}{2} u^\tau u = \frac{u^2}{2}$ so that $(u, v) \in H(L, L_2)_l$. We get $x^\tau u - u^\tau x = u(x - {}^\tau x) = w$. \square

3 Bruhat-Tits theory for quasi-split semisimple groups

In Bruhat-Tits theory, a building is attached to a reductive group in two steps. The first step, in [BrT84, §4], corresponds to split and quasi-split groups. The second step in [BrT84, §5] is an étale descent to the base field. In order to describe some subgroups in terms of the action on the Bruhat-Tits building, in Section 3.1, we recall how the simplicial structure of the building is defined thanks to the valuation of root groups. Then, in Section 3.2, we consider the action of the group $G(K)$ on its Bruhat-Tits building $X(G, K)$. In this section, K is a local field and G is an almost- K -simple simply-connected quasi-split K -group.

3.1 Numerical description of walls and alcoves

The Bruhat-Tits building of (G, K) is obtained by gluing together affine spaces, called apartments, having the same given simplicial structure. This consists in defining the building as $X(G, K) = G(K) \times \mathbb{A} / \sim$, where \mathbb{A} is a suitable affine space, called the standard apartment, see [Lan96, §9]. The apartments are glued together along hyperplanes called walls, that we will describe as zero sets of affine functions thanks to the sets of values defined in Section 2.1.5. In Section 3.1.1, we recall how we deduce the simplicial structure of an apartment from the definition of walls. More precisely, we define an “affinisation” of the spherical root system following the Bruhat-Tits method. In Lemma 3.1.13, we check that this construction coincide with the affine root system defined by Tits in [Tit79]. In Section 3.1.2, we describe, thanks to the sets of values, a well-chosen alcove, which is the candidate to be a fundamental domain of the action of $G(K)$ on $X(G, K)$. In Section 3.1.3, we look locally the building near an alcove.

3.1.1 Walls of an apartment of the Bruhat-Tits building

In [Lan96, §1], we define a simplicial structure for apartments as follows. Firstly, we let $\mathbb{A} = \mathbb{A}(G, S, K)$ be the unique affine space under $V = X_*(S) \otimes_{\mathbb{Z}} \mathbb{R}$ together with a suitable group homomorphism $\nu : \mathcal{N}_G(S)(K) \rightarrow \text{Aff}(\mathbb{A})$.

Secondly, each relative root $a \in \Phi \subset X^*(S)$ induces a linear form on V deduced by linearity from the dual pairing $X_*(S) \times X^*(S) \rightarrow \mathbb{Z}$. Hence, up to choice of an origin $\mathcal{O} \in \mathbb{A}$, each relative root induces an affine map on \mathbb{A} .

Thirdly, any relative root $a \in \Phi \subset X^*(S)$ can be seen as a linear form on $V = X_*(S) \otimes_{\mathbb{Z}} \mathbb{R}$, arising from the dual pairing $\langle \cdot, \cdot \rangle : X^*(S) \times X_*(S) \rightarrow \mathbb{R}$. From this spherical root system (where each root is seen as a linear form), we define an “affinisation”. Hence, each affine map $\theta(a, l) = a(\cdot - \mathcal{O}) - l : \mathbb{A} \rightarrow \mathbb{R}$, where $a \in \Phi$ and $l \in \mathbb{R}$, determinates a unique **half-apartment** denoted by:

$$D(a, l) = \{x \in \mathbb{A}, \theta(a, l)(x) > 0\}$$

whose border (an affine subspace of codimension one) is denoted by $\mathcal{H}_{a, l} = \{x \in \mathbb{A}, \theta(a, l)(x) = 0\}$. When $l \in \Gamma'_a$, the affine map $\theta(a, l)$ is called an **affine root**. In Lemma 3.1.13, we will see that the set of affine roots is the affine root system of [Tit79, 1.6].

For each affine root $\theta(a, l)$, the corresponding $\mathcal{H}_{a, l}$ is called a **wall** of \mathbb{A} . The walls induce a structure of poly-simplicial complex on \mathbb{A} : a connected

component of $\mathbb{A} \setminus \bigcup_{a \in \Phi, l \in \Gamma'_a} \mathcal{H}_{a,l}$ is called an **alcove**. It is a simplex of maximal dimension. More generally, we define an equivalence relation on points on \mathbb{A} by $x \sim y$ if, for any $a \in \Phi$, if the real numbers $a(x)$ and $a(y)$ have the same sign or are both equal to zero. That means $x \sim y$ if, and only if, x and y always are in the same half-apartment. An equivalence class is called a **facet**; alcoves are the facets of maximal dimension. The set of facets constitutes a partition of \mathbb{A} . Finally, the affine space \mathbb{A} together with the affine root system $\{\theta(a, l), a \in \Phi \text{ and } l \in \Gamma'_a\}$ and the structure of poly-simplicial complex deduced from the walls is called the **standard apartment**.

3.1.1 Notation. For any non-empty bounded subset Ω of \mathbb{A} , according to [BrT84, §4] and [Lan96, §5], we denote:

- $f_\Omega(a) = \sup\{-a(x), x \in \Omega\}$ for any relative root $a \in \Phi$;
- $U_{a,\Omega} = U_{a,f_\Omega(a)}$ for any relative root $a \in \Phi$;
- $f'_\Omega(a) = \inf\{l \in \Gamma'_a, l \geq f_\Omega(a) \text{ or } \frac{1}{2}l \geq f_\Omega(\frac{a}{2})\}$
 $= \sup\{l \in \mathbb{R}, U_{a,l} = U_{a,f_\Omega(a)}\}$
- U_Ω the subgroup of $G(K)$ generated by the groups $U_{a,\Omega}$ where $a \in \Phi$;
- $N_\Omega = \{n \in \mathcal{N}_G(S)(K), \forall x \in \Omega, n \cdot x = x\}$;
- $P_\Omega = U_\Omega \cdot T(K)_b$, (we recall that $T(K)_b$ normalizes U_Ω);
- \widehat{P}_Ω the subgroup of $G(K)$ generated by U_Ω and N_Ω .

Moreover, because G is a (quasi-split) semisimple K -group, the group \widehat{P}_Ω can be realized as the integral points of a suitable model \mathfrak{G}_Ω of G , and we write $\widehat{P}_\Omega = \mathfrak{G}_\Omega^\circ(\mathcal{O}_K)$. This group is the connected pointwise stabilizer in $G(K)$ of the subset $\Omega \subset X(G, K)$ [BrT84, 4.6.28].

From the dual pairing, each relative root $a \in \Phi$ can be realized geometrically in the Euclidean dual space V^* . By [Bou81, VI.1.4 Prop. 12], there are exactly one or two values for the length of a root if Φ is reduced; and by [Bou81, VI.4.14] there are three values if Φ is non-reduced. We say that a root $a \in \Phi$ is a **long root** if its length is maximal in its irreducible component, and is a **short root** otherwise. More precisely, if Φ is a reduced non-simply laced root system, the ratio between the length of a long root and the length of a short root is exactly $\sqrt{d'}$ where the integer $d' \in \{1, 2, 3\}$ has been defined in 2.1.4 considering the smallest extension of K splitting G .

3.1.2 Proposition. *Let d, L', L_d as in 2.1.4.*

- (1) *If $d = 1$, every root $a \in \Phi$ has $L_a = L' = L_d = L_0$ as splitting field (up to isomorphism, in the sense of 2.1.6).*
- (2) *If $d \geq 2$ and Φ is reduced, every short root has L' as splitting field; every long root has L_d as splitting field.*
- (3) *If $d = 2$ and Φ is non-reduced, every non-divisible root has L' as splitting field; every divisible root has L_d as splitting field.*

Proof. (1) If $d = 1$, then $\Sigma_0 = \Sigma_d = \Sigma_a$ for any root $a \in \Phi$. Hence, we have the equality of the corresponding fixed fields $L_0 = L_d = L_a = L'$.

Suppose now that $d \geq 2$. Because $\text{Dyn}(\widetilde{\Delta})$ has a non-trivial symmetry, all the absolute roots have the same length in the geometric realisation in \widetilde{V}^* defined in 2.1.3. Let a be a relative root, seen as orbit, which contain several absolute roots. In the geometric realization, the orbit a can be geometrically realized as the orthogonal projection of its absolute roots. Hence, the length

of the orbits having several roots is shorter than that of the orbits having only one root.

Let $a \in \Phi$ be a relative root and let $\alpha \in \tilde{\Phi}$ be an absolute root so that the relative root $a = \alpha|_S$ is its orbit for the $*$ -action.

(2) If $d \geq 2$ and Φ is reduced. If a is short, then Σ_0 fixes α but Σ_d does not. Moreover, we observe that for $d = 6$ (hence $\tilde{\Phi}$ is of type D_4), the stabilizer of α in $\Sigma_d/\Sigma_0 \simeq \mathfrak{S}_3$ has index 3. Hence L_α is a separable extension of L_d of degree 3 if $d \geq 3$ and of degree 2 otherwise, hence isomorphic to L' . Thus $L' = L_a$. If a is long, then Σ_d is the stabilizer of α . Hence $L_d = L_a$.

(3) If $d = 2$ and Φ is non-reduced. If a is divisible, then a is a long root. Hence Σ_2 is the stabilizer of α . Thus $L_2 = L_a$. Otherwise, a is a short root. Hence Σ_0 is the stabilizer of α . Thus $L' = L_0 = L_a$. \square

3.1.2 Description of an alcove by its panels

An alcove is the candidate to be a fundamental domain of the action of $G(K)$ on its Bruhat-Tits building $X(G, K)$.

3.1.3 Definition. A **panel** is a facet of $X(G, S)$ of codimension 1.

We want to describe precisely, thanks to some relative roots and their sets of values, walls bounding a given alcove. To do this, we may have to consider a dual root system, which appears to be necessary in some ramified cases.

Firstly, we define a dual root system of Φ by a suitable normalisation of the canonical dual root system in Lie considerations.

3.1.4 Notation. We consider a geometric realization of Φ_{nd} in the Euclidean space $(V^*, (\cdot|\cdot))$. For each root $a \in \Phi_{\text{nd}}$, we set $\lambda_a = \frac{\mu^2}{(a|a)} \in \{1, d'\}$ and $a^D = \lambda_a a \in V$ where μ is the length of a long root, so that $a^D = a$ for any long roots. The set $\Phi_{\text{nd}}^D = \{a^D, a \in \Phi_{\text{nd}}\}$ is a root system, because it is proportional (by a factor $\frac{\mu^2}{2}$) to the dual root system Φ^\vee of [Bou81, VI.1.1 Prop. 2]. In particular, if Φ is a reduced irreducible root system, then $\Phi^D = \Phi$ if, and only if, it is a simply laced root system (type A , D , or E). Moreover, by [Bou81, VI.1.5 Rem.(5)], if Δ is a basis of Φ , then $\Delta^D = \{a^D, a \in \Delta\}$ is a basis of Φ_{nd}^D .

Whereas Φ^\vee and Φ^D are constructions strictly in terms of Lie theory, we have found it was more convenient to introduce the following root system Φ^δ which takes into account the splitting field extensions of root groups.

3.1.5 Definition. For any non-divisible root $a \in \Phi_{\text{nd}}$, we denote by $\delta_a \in \{1, d'\}$ the order of the quotient group $\Gamma_{L_a}/\Gamma_{L_d}$ (resp. $\Gamma_{L_a}/\Gamma_{L'}$) if Φ is reduced (resp. non-reduced), by $a^\delta = \delta_a a$ and by $\Phi_{\text{nd}}^\delta = \{a^\delta, a \in \Phi_{\text{nd}}\}$. We denote by $\Delta^\delta = \{a^\delta, a \in \Delta\}$. We will see below that $\Phi_{\text{nd}}^\delta = \Phi_{\text{nd}}$ or Φ_{nd}^D .

3.1.6 Notation. In the following, we denote by:

- h the highest root of Φ with respect to the chosen basis Δ ;
- $\theta \in \Phi_{\text{nd}}$ the root such that θ^δ is the highest root of Φ_{nd}^δ with respect to the basis Δ^δ .

Moreover, if Φ is non-reduced, we will see below that $\Phi_{\text{nd}}^\delta = \Phi_{\text{nd}}^D = \Phi_{\text{nm}}$, so that $h = 2\theta$.

Note that if a is multipliable and $2l \in \Gamma'_{2a}$, it is possible that $\mathcal{H}_{2a, 2l} = \mathcal{H}_{a, l}$ be a wall even if $l \notin \Gamma'_a$. Moreover, we have $\Gamma_a = \Gamma'_a \cup \frac{1}{2}\Gamma'_{2a}$ in this case.

Otherwise, if a is non-multipliable and non divisible, we have $\Gamma_a = \Gamma'_a$ by Lemma 2.1.12. In fact, the walls of \mathbb{A} are described by the various $a \in \Phi_{\text{nd}}$ and $l \in \Gamma_a$.

According to [BrT84, 4.2.23], we can classify the scalings to describe the various alcoves for a K -simple group G . In a similar way, there exists a classification of (quasi-split) absolutely almost-simple groups over a local field, provided by Tits in [Tit79, §4]. Here, we reduce the discussion to three types of behaviours.

First case: Φ is reduced and L'/L_d is unramified. These groups are the residually split groups named $A_n, B_n, C_n, D_n, E_6, E_7, E_8, F_4$ and G_2 ; and the non-residually split groups named ${}^2A'_{2n-1}, {}^2D_{n+1}, {}^2E_6$ and 3D_4 in the Tits tables [Tit79, 4.2, 4.3]. These correspond respectively to scalings, classified in [BrT72, 1.4.6], of type $A_n, B_n, C_n, D_n, E_6, E_7, E_8, F_4$ and G_2 ; and C_n, B_n, F_4 and G_2 .

Let a be a relative root. Because Φ is reduced, $\Gamma_a = \Gamma_{L_a}$ by Lemma 2.1.12. Hence, by Proposition 3.1.2, we have $\Gamma_a = \Gamma_{L_d}$. Because L'/L_d is unramified, we have $\Gamma_{L'} = \Gamma_{L_d}$. Hence $\Phi^\delta = \Phi$ and $h = \theta$.

In order to simplify notations, we normalize the valuation ω so that $\Gamma_{L'} = \mathbb{Z} = \Gamma_{L_d}$ and $0^+ = 1$. By definition of alcoves as connected components, we can define an alcove as the intersection of all the various half-apartments $D(a, l)$ and $D(b, l^+)$ where $a \in \Phi^+, b \in \Phi^-$ and $l \in \mathbb{R}^+$. Because $D(A, l) \subset D(a, l')$ for any $l > l'$, we are in fact considering the finite intersection of all the various half-apartments $D(a, 0)$ and $D(b, 1)$ where $a \in \Phi^+$ and $b \in \Phi^-$. We call it “the” fundamental alcove, denoted by c_{af} .

By [Bou81, VI.2.2 Prop. 5], its panels are exactly contained inside the walls $\mathcal{H}_{a,0}$, where $a \in \Delta$, and $\mathcal{H}_{-h,1}$.

3.1.7 Example (The apartments and their fundamental alcoves in dimension 2).

Second case: Φ is reduced and L'/L_d is ramified. These groups are the residually split groups named $B-C_n, C-B_n, F_4^I$ and G_2^I in the Tits tables [Tit79, 4.2]. These correspond respectively to scalings, classified in [BrT72, 1.4.6], of type $B-C_n, C-B_n, F_4^I$ and G_2^I .

Because L'/L_d is ramified, $d' \in \{2, 3\}$, hence Φ is a non-simply laced root system. Moreover, we have $d'\Gamma_{L'} = \Gamma_{L_d}$. Let a be a relative root. Because Φ is reduced, $\Gamma_a = \Gamma_{L_a}$ by Lemma 2.1.12. By Proposition 3.1.2, if a is a long root, $\Gamma_a = \Gamma_{L_d}$; if a is a short root, $\Gamma_a = \Gamma_{L'}$. Thus, $\delta_a = \lambda_a$. Hence $\Phi_{\text{nd}}^\delta = \Phi_{\text{nd}}^D$.

In order to simplify notations, we normalize the valuation ω so that $\Gamma_{L'} = \mathbb{Z}$. The intersection of all the various half-apartments $D(a, 0)$ and $D(b, 0^+)$ where $a \in \Phi^+$ and $b \in \Phi^-$ in exactly an alcove. If $b \in \Phi^-$ is short, then $\Gamma_b = \Gamma_{L'}$ so that $D(b, 0^+) = D(b, 1)$; if $b' \in \Phi^-$ is long, then $\Gamma_b = \Gamma_{L_d}$ so that $D(b, 0^+) = D(b', d')$. We call it “the” fundamental alcove, denoted by \mathbf{c}_{af} .

Its panels are exactly contained inside the walls $\mathcal{H}_{a,0}$, where $a \in \Delta$, and $\mathcal{H}_{-\theta,1}$. Indeed, let $a \in \Phi$ and $l \in \mathbb{R}$. Let $l^D = \delta_a l$ so that for any $x \in \mathbb{A}$:

$$a(x - \mathcal{O}) - l = 0 \Leftrightarrow a^D(x - \mathcal{O}) - l^D = 0$$

By definition, the set $\mathcal{H}_{a,l}$ is a wall of \mathbb{A} if, and only if, $l \in \Gamma_a$; hence if, and only if, $l^D \in \Gamma_{L_d}$. Thus, the panels of \mathbf{c}_{af} are contained in the walls \mathcal{H}_{a^D, l^D} described in the first case. Because the highest root θ^D is a long root in Φ^D by [Bou81, VI.1.8 Prop. 25 (iii)], hence θ is a short root in Φ and $\delta_\theta = d'$.

3.1.8 Remark. The ramification as the effect of adding some walls in the direction corresponding to short roots. For instance, if $d = 2$ and if the absolute root system $\tilde{\Phi}$ is of type A_3 , then the relative root system is of type C_2 and we obtain the following picture where we print the “added” walls with dotted lines, and the root system Φ^D instead of Φ :

Third case: Φ is non-reduced. These groups are named $C\text{-}BC_n$ and ${}^2A'_{2n}$ in the Tits tables [Tit79, 4.2, 4.3]. These correspond respectively to scalings, classified in [BrT72, 1.4.6], of type $C\text{-}BC_n^{III}$ and $C\text{-}BC_n^{IV}$.

Because Φ is non-reduced, $d = d' = 2$. In order to simplify notations, we normalize the valuation ω so that $\Gamma_{L'} = \mathbb{Z}$. Let a be a non-divisible relative root. If a is multipliable, by Lemma 2.1.13, we have $\Gamma_a = \frac{1}{2}\Gamma_{L'}$; if a is non-multipliable, by Lemma 2.1.12, and by Proposition 3.1.2, we have $\Gamma_a = \Gamma_{L_a} = \Gamma_{L'}$. Thus, $\delta_a \Gamma_a = \Gamma_{L'}$.

As above, one can see that the intersection of all the various following half-apartments: $D(a, 0)$ where $a \in \Phi_{\text{nd}}^+$, $D(b, 1)$ where $b \in \Phi_{\text{nd}}^-$ is non-multipliable, and $D(b', \frac{1}{2})$ where $b' \in \Phi^-$ is multipliable, is exactly an alcove. We call it “the” fundamental alcove, denoted by \mathbf{c}_{af} . Its panels are exactly contained inside the walls $\mathcal{H}_{a,0}$, where $a \in \Delta$, and $\mathcal{H}_{-\theta, \frac{1}{2}}$.

Indeed, we proceed in the same way as in the previous case, with the reduced root system Φ_{nd}^D .

3.1.9 Example ($\tilde{\Phi}$ of type A_4 and Φ of type BC_2).

3.1.3 Counting alcoves of a panel residue

Because a maximal pro- p subgroup P fixes an alcove \mathbf{c} , it acts on the set of alcoves which are adjacent to \mathbf{c} . We want to describe this set of alcoves.

3.1.10 Definition. Let F be a panel. The **panel residue** with respect to F , denoted by E_F , is the set of the alcoves whose the closure contains F .

The **combinatorial unit ball** centered in \mathbf{c} , denoted by $B(\mathbf{c}, 1)$, is the union of all the panel residues with respect to a panel F in the closure of \mathbf{c} .

We say that two alcoves are **adjacent** if they have a common panel.

In what follows, we provide a reformulation and a proof of [Tit79, 1.6].

3.1.11 Proposition. Let $a \in \Phi$ and $l \in \Gamma_a$. The group U_{a,l^+} is a normal subgroup of $U_{a,l}$. We denote by $X_{a,l} = U_{a,l}/U_{a,l^+}$ the quotient group.

If a is non-multipliable, then there exists a canonical κ_{L_a} -vector space structure on $X_{a,l}$ of dimension 1.

If a is multipliable, then there exists a canonical group homomorphism $X_{2a,2l} \rightarrow X_{a,l}$; so that we have the inclusion $[X_{a,l}, X_{a,l}] \leq X_{2a,2l}$. There exists a canonical κ_{L_a} -vector space structure on the quotient group $X_{a,l}/X_{2a,2l}$ of dimension 0 or 1.

Proof. Suppose that a is non-multipliable, then $U_a(K)$ is commutative. Hence U_{a,l^+} is a normal subgroup of $U_{a,l}$ and the quotient group $X_{a,l}$ is commutative. We define a \mathcal{O}_{L_a} -module structure on $X_{a,l}$ by:

$$\forall x \in \mathcal{O}_{L_a}, \forall y \in L_a \text{ such that } \omega(y) \geq l, x \cdot x_a(y)U_{a,l^+} = x_a(xy)U_{a,l^+}$$

For any $x \in \varpi_{L_a} \mathcal{O}_{L_a}$ and any $y \in L_a$ such that $\omega(y) \geq l$, we have $\omega(xy) \geq l^+$, hence $xX_{a,l} \leq U_{a,l^+}$. This provides a $\kappa_{L_a} = \mathcal{O}_{L_a}/\varpi_{L_a} \mathcal{O}_{L_a}$ -vector space structure on $X_{a,l}$. We check that this vector space is of dimension 1: for any $y, y' \in L_a$ such that $\omega(y) = \omega(y') = l$, since y is invertible, we have $x = y^{-1}y' \in \mathcal{O}_{L_a}$. Moreover, such elements y, y' exist by definition of Γ_{L_a} .

Suppose now that a is multipliable. By Lemma 2.3.12 applied to $l, l^+ \in \Gamma_a$, we get that U_{a,l^+} is a normal subgroup of $U_{a,l}$.

The normal subgroup $U_{2a,2l^+}$ of $U_{2a,2l}$ is the kernel of the canonical group homomorphism $U_{2a,2l} \rightarrow X_{a,l}$. Hence we deduce a quotient group homomorphism $X_{2a,2l} \rightarrow X_{a,l}$. Passing to the quotient the formula of Lemma 2.3.12, we get $[X_{a,l}, X_{a,l}] \leq X_{2a,2l}$.

In particular, the group $X_{a,l}/X_{2a,2l}$ is commutative. There exist an \mathcal{O}_{L_a} -module structure given by:

$$\forall x \in \mathcal{O}_{L_a}, \forall (y, y') \in H(L_a, L_{2a}) \text{ such that } \omega(y') \geq 2l, \\ x \cdot x_a(y, y')U_{a,l^+}U_{2a,2l} = x_a(xy, x^\tau xy')U_{a,l^+}U_{2a,2l}$$

For any $x \in \varpi_{L_a}\mathcal{O}_{L_a}$ and any $(y, y') \in H(L_a, L_{2a})$ such that $\omega(y') \geq 2l$, we have $\omega(x^\tau xy') \geq 2(l^+)$. This defines a κ_{L_a} -vector-space structure on $X_{a,l}/X_{2a,2l}$. This vector-space is of dimension at most 1. Indeed, if there exist elements $(y, y'), (z, z') \in H(L_a, L_{2a})$ such that $\omega(y') = \omega(z') = 2l$, then we can set $x = y^{-1}z \in \mathcal{O}_{L_a}$ because y is invertible. Hence, we have $x_a(z, z') \in x \cdot x_a(y, y')U_{2a,2l}$. \square

If a is a non-multipliable root, we set $X_{2a,2l} = 0$ and $\kappa_{L_{2a}} = \kappa_{L_a}$. Hence, the dimension $d(a, l) = \dim_{\kappa_{L_{2a}}} X_{a,l}/X_{2a,2l}$ has a sense for any root $a \in \Phi$.

3.1.12 Remark. Let F be a panel contained in a wall $\mathcal{H}_{a,l}$ corresponding to an affine root $\theta(a, l)$. Denote $q = \text{Card}(\kappa_{L_{2a}})$. The panel residue E_F contains $1 + \text{Card}(X_{a,l}) = 1 + q^{d(\frac{a}{2}, \frac{l}{2}) + d(a, l) + d(2a, 2l)}$ elements. This is a consequence of Lemma 3.2.3.

The following lemma states that the affine root systems defined in [BrT72, 6.2.6] and in [Tit79, 1.6] are the same.

3.1.13 Lemma. *Let $a \in \Phi$ be a root and $l \in \mathbb{R}$. Then $d(a, l) > 0$ if, and only if, $l \in \Gamma'_a$.*

Proof.

$$\begin{aligned} l \in \Gamma'_a &\Leftrightarrow \exists \mathbf{u} \in U_a(K), \varphi_a(\mathbf{u}) = l = \sup \varphi_a(\mathbf{u}U_{2a}(K)) \\ &\Leftrightarrow \exists \mathbf{u} \in U_a(K), \varphi_a(\mathbf{u}) = l \text{ and } \forall \mathbf{u}'' \in U_{2a}(K), \varphi_a(\mathbf{u}\mathbf{u}'') < l^+ \\ &\Leftrightarrow U_{a,l} \neq U_{a,l^+} \text{ and } \exists \mathbf{u} \in U_{a,l}, \forall \mathbf{u}'' \in U_{2a}(K), \mathbf{u}\mathbf{u}'' \notin U_{a,l^+} \\ &\Leftrightarrow X_{a,l} \neq 0 \text{ and } X_{a,l} \neq X_{2a,2l} \\ &\Leftrightarrow d(a, l) \neq 0 \end{aligned}$$

\square

This affine root system is an affinisation of the spherical root system. It can be obtained by adding affine reflections corresponding to elements $\mathbf{m}(u) = u'uu''$ where for any $u \in U_a(K) \setminus \{1\}$, there exist $u', u'' \in U_{-a}K$ uniquely determined such that $\mathbf{m}(u) \in \mathcal{N}_G(S)(K)$.

3.2 Action on a combinatorial unit ball

We consider a maximal pro- p -subgroup $P = P_{\mathbf{c}}^+$ of $G(K)$. For any $a \in \Phi$, if there exists a wall $\mathcal{H}_{a,l}$ bounding \mathbf{c} , we denote by $F_{\mathbf{c},a}$ the panel of \mathbf{c} contained in $\mathcal{H}_{a,l}$. Let $E_{\mathbf{c},a} = E_{F_{\mathbf{c},a}}$ be the panel residue of $F_{\mathbf{c},a}$. We want to study the action of the derived group and of the Frattini subgroup of P on the Bruhat-Tits building $X(G, K)$ of G over K . For this, we consider the action, on each set $E_{\mathbf{c},a}$, of the various valued root groups $U_{a,c}$ and of the group $T(K)_b^+$.

3.2.1 Lemma. *Let \mathbf{c}_1 and \mathbf{c}_2 be two adjacent alcoves of the apartment \mathbb{A} along a wall directed by a root $a \in \Phi$. If $b \in \Phi \setminus \mathbb{R}a$, then $f'_{\mathbf{c}_1}(b) = f'_{\mathbf{c}_2}(b)$ where f' is defined in 3.1.1. In particular, we have $U_{b,\mathbf{c}_1} = U_{b,\mathbf{c}_2}$.*

Proof. In order that $f'_{\mathbf{c}_1}(b) \neq f'_{\mathbf{c}_2}(b)$, it is necessary and sufficient that there exists a wall directed by b separating the alcoves \mathbf{c}_1 and \mathbf{c}_2 in two opposed half-apartments. The alcoves \mathbf{c}_1 and \mathbf{c}_2 contain a panel contained in a wall

directed by a . This wall is the only one separating the alcoves in two opposed half-apartments. Hence, if $f'_{c_1}(b) \neq f'_{c_2}(b)$, then a and b are collinear. \square

3.2.2 Proposition. *Let $a \in \Phi = \Phi(G, S)$ be a relative root such that there exists a wall $\mathcal{H}_{a,l}$ bounding \mathbf{c} . If a is non-multipliable or if the quadratic extension L_a/L_{2a} is ramified, then the Frattini subgroup $\text{Frat}(P)$ fixes $E_{\mathbf{c},a}$ pointwise.*

As a consequence, if Φ is a reduced root system or if the extension L/L_d is ramified, then $\text{Frat}(P)$ fixes pointwise the simplicial closure $\text{cl}(B(\mathbf{c}, 1))$ of the combinatorial unit ball.

In general, denoting by Q_a the pointwise stablizer of $E_{\mathbf{c},a}$, we have the group inclusion $\text{Frat}(P) \subset Q_a U_{2a, \mathbf{c}}$.

The rest of this section consists in proving the above proposition.

Let \mathbf{c}' be an alcove of \mathbb{A} adjacent to \mathbf{c} . In particular, we have $\mathbf{c}' \in B(\mathbf{c}, 1)$. Write $a' + r'$, with $a' \in \Phi$ and $r' \in \Gamma_{a'}$, the affine root directing the wall separating the alcoves \mathbf{c} and \mathbf{c}' . If a' is divisible, we set $a = \frac{1}{2}a'$ and $r = \frac{1}{2}r'$. Remark that we still have $r \in \Gamma_a$ but $a + r$ may or may not be an affine root according to r is an element of Γ'_a or not. Otherwise, we set $a = a'$ and $r = r'$. We also have the following definition of r by the equality $r = f_{\mathbf{c}}(a) = f'_{\mathbf{c}}(a)$ by [Lan96, 7.7]. Up to exchanging a and $-a$, one can assume that $f_{\mathbf{c}'}(a) = f_{\mathbf{c}}(a)^+ > f_{\mathbf{c}}(a)$ and that $f_{\mathbf{c}'}(-a) < f_{\mathbf{c}}(-a) = f_{\mathbf{c}'}(-a)^+$.

The group P acts on the finite set of alcoves $E_{\mathbf{c},a}$ and fixes \mathbf{c} . Hence, it acts on the set of alcoves $E'_{\mathbf{c},a} = E_{\mathbf{c},a} \setminus \{\mathbf{c}\}$. Denote by Q_a the kernel of this action. We will show that the quotient group P/Q_a is isomorphic to a subgroup of $U_{a,r}/U_{a,r^+}$.

3.2.3 Lemma. *The group $U_{a,\mathbf{c}}$ acts transitively on the set $E'_{\mathbf{c},a}$.*

Proof. By construction of the building, the subgroup $P_{\mathbf{c}}$ acts transitively on the set of apartments containing \mathbf{c} [Lan96, 9.7 (i)]. Because the action preserves the type of facets, we obtain $E_{\mathbf{c},a} = P_{\mathbf{c}} \cdot \mathbf{c}'$.

Write $P_{\mathbf{c}} = U_{a,\mathbf{c}} \cdot \prod_{b \in \Phi_{\text{nd}}^+ \setminus \{a\}} U_{b,\mathbf{c}} \cdot U_{-\Phi^+, \mathbf{c}} \cdot T(K)_b$ [BrT72, 7.1.8]. The group $T(K)_b$ fixes A pointwise [Lan96, 9.8], hence it also fixes \mathbf{c}' . For any $b \in \Phi \setminus \mathbb{R}_a$, by Lemma 3.2.1 we have $U_{b,\mathbf{c}} = U_{b,\mathbf{c}'}$. Hence $U_{b,\mathbf{c}}$ fixes \mathbf{c}' . Since we assumed that $f_{\mathbf{c}'}(-a) < f_{\mathbf{c}}(-a)$, we have $U_{-a,\mathbf{c}} \subset U_{-a,\mathbf{c}'}$. Hence $U_{-a,\mathbf{c}}$ fixes \mathbf{c}' . As a consequence $E'_{\mathbf{c},a} = U_{a,\mathbf{c}} \cdot \mathbf{c}'$, because the valued root groups $U_{b,\mathbf{c}}$ and the group $T(K)_b$ fix \mathbf{c}' . \square

3.2.4 Lemma. *Let $g \in P$ be an element fixing \mathbf{c}' . If $[v, g]$ fixes \mathbf{c}' for any $v \in U_{a,\mathbf{c}}$, then g fixes $E_{\mathbf{c},a}$.*

Proof. Let $\mathbf{c}'' \in E'_{\mathbf{c},a}$. By Lemma 3.2.3, there exists an element $v \in U_{a,\mathbf{c}}$ such that $\mathbf{c}'' = v\mathbf{c}'$. We do the following computation:

$$\begin{aligned} g \cdot \mathbf{c}'' &= gv \cdot \mathbf{c}' \\ &= v[v^{-1}, g]g \cdot \mathbf{c}' \\ &= v[v^{-1}, g] \cdot \mathbf{c}' && \text{because } g \text{ fixes } \mathbf{c}' \\ &= v\mathbf{c}' && \text{because } [v^{-1}, g] \text{ fixes } \mathbf{c}' \\ &= \mathbf{c}'' \end{aligned}$$

Since this is true for any $\mathbf{c}'' \in E'_{\mathbf{c},a}$, we conclude that g fixes $E_{\mathbf{c},a}$. \square

Hence, to show that $g \in [P, P]$ fixes $E_{\mathbf{c},a}$, it suffices to verify that $[U_{a,\mathbf{c}}, g]$ fixes \mathbf{c}' . We are reduced to compute commutators. Recall that the group $U_{a, f_{\mathbf{c}}(a)^+} = U_{a,\mathbf{c}'}$ fixes \mathbf{c}' .

3.2.5 Lemma. *The following groups:*

1. $U_{a, f_{\mathbf{c}}(a)^+}$
2. $T(K)_b^+$
3. $U_{b, \mathbf{c}}$ where $b \in \Phi \setminus \mathbb{R}a$
4. $U_{-a, \mathbf{c}}$

fix the panel residue $E_{\mathbf{c}, a}$.

Proof. (1) Let $u \in U_{a, f_{\mathbf{c}}(a)^+}$. Then u fixes \mathbf{c}' . Let $v \in U_{a, \mathbf{c}}$.

If a is non-multipliable, then $[v, u] = 1$ because the root group $U_a(K)$ is commutative.

If a is multipliable, by Lemma 2.3.12, we know that $[v^{-1}, u] \in U_{2a, [f_{\mathbf{c}}(a)^+] + [f_{\mathbf{c}}(a)]}$. Since $[f_{\mathbf{c}}(a)^+] + [f_{\mathbf{c}}(a)] > 2f_{\mathbf{c}}(a)$, we deduce that $[v^{-1}, u] \in U_{a, f_{\mathbf{c}}(a)^+} = U_{a, f_{\mathbf{c}'}(a)}$ fixes \mathbf{c}' .

Applying Lemma 3.2.4, we obtain that u fixes $E_{\mathbf{c}, a}$.

(2) Let $t \in T(K)_b^+$. The element t fixes \mathbf{c}' because $T(K)_b$ fixes the apartment A . By Lemmas 2.2.1 and 2.3.4, we know that $[T(K)_b^+, U_{a, \mathbf{c}}] \subset U_{a, f_{\mathbf{c}}(a)^+} = U_{a, \mathbf{c}'}$. Hence $[v, t] \in U_{a, \mathbf{c}'}$ fixes \mathbf{c}' for any $v \in U_{a, \mathbf{c}}$. We deduce from (1) that $T(K)_b^+$ fixes $E_{\mathbf{c}, a}$.

(3) Let $g \in U_{b, \mathbf{c}}$ and $v \in U_{a, \mathbf{c}}$. By Lemma 3.2.1, we get $U_{b, \mathbf{c}} = U_{b, \mathbf{c}'}$. Hence $g \cdot \mathbf{c}' = \mathbf{c}'$. By quasi-concavity of the functions f' applied in the case where a and b are not collinear, we get by [BrT84, 4.5.10]:

$$[v^{-1}, g] \in \prod_{m, n \in \mathbb{N}^*, ma+nb \in \Phi} U_{ma+nb, f'_{\mathbf{c}}(ma+nb)}$$

Applying again Lemma 3.2.1, we get $U_{ma+nb, \mathbf{c}} = U_{ma+nb, \mathbf{c}'}$. Thus $[v, g]$ fixes \mathbf{c}' for any v , hence, by Lemma 3.2.4, the element g fixes $E_{\mathbf{c}, a}$.

(4) Let $u \in U_{-a, \mathbf{c}}$ and $v \in U_{a, \mathbf{c}}$. Since $f_{\mathbf{c}'}(-a) < f_{\mathbf{c}}(-a)$, we get $U_{-a, \mathbf{c}} \subset U_{-a, \mathbf{c}'}$. Hence u fixes \mathbf{c}' .

According to whether a is multipliable or not, we know that $[v, u] \subset U_{-a, f_{\mathbf{c}}(-a)^+} T(K)_b^+ U_{a, f_{\mathbf{c}}(a)^+}$, by applying either Lemma 2.3.6 or Lemma 2.2.2. The groups $U_{a, f_{\mathbf{c}}(a)^+}$, $T(K)_b^+$, and $U_{-a, f_{\mathbf{c}}(-a)^+} \subset U_{-a, f_{\mathbf{c}}(-a)}$ fix \mathbf{c}' . Thus, the commutator $[v, u]$ fixes \mathbf{c}' because it can be written as the product of three such elements. Applying lemma 3.2.4, we conclude that u fixes $E_{\mathbf{c}, a}$. \square

Proof of Proposition 3.2.2. We keep notations introduced below Proposition 3.2.2. In particular, a is a root such that there exists a wall $\mathcal{H}_{a, l}$ bounding the alcove $\mathbf{c} \subset \mathbb{A}$; the alcove $\mathbf{c}' \in \mathbb{A}$ has the panel $F_{\mathbf{c}, a}$ in common with \mathbf{c} . We have the equalities $f'_{\mathbf{c}}(a)^+ = f'_{\mathbf{c}'}(a) = f'_{\mathbf{c} \cup \mathbf{c}'}(a)$. Hence $U_{a, f_{\mathbf{c}}(a)^+} = U_{a, \mathbf{c} \cup \mathbf{c}'}$. For any root $b \in \Phi_{\text{nd}} \setminus \mathbb{R}a$, by Lemma 3.2.1, we get $f'_{\mathbf{c}}(b) = f'_{\mathbf{c}'}(b) = f'_{\mathbf{c} \cup \mathbf{c}'}(b)$. Hence $U_{b, f_{\mathbf{c}}(b)} = U_{b, \mathbf{c} \cup \mathbf{c}'}$. Finally, because we have assumed $f'_{\mathbf{c}'}(-a) < f'_{\mathbf{c}}(-a)$, we get the equality of groups $U_{-a, \mathbf{c} \cup \mathbf{c}'} = U_{-a, f'_{\mathbf{c}}(-a)} \cap U_{-a, f'_{\mathbf{c}'}(-a)} = U_{-a, \max(f'_{\mathbf{c}}(-a), f'_{\mathbf{c}'}(-a))} = U_{-a, \mathbf{c}}$. From this, we deduce the equality of groups:

$$U_{a, f_{\mathbf{c}}(a)^+} \left(\prod_{b \in \Phi_{\text{nd}} \setminus \{a\}} U_{b, \mathbf{c}} \right) T(K)_b^+ U_{-\Phi^+, \mathbf{c}} = U_{\Phi^+, \mathbf{c} \cup \mathbf{c}'} T(K)_b^+ U_{-\Phi^+, \mathbf{c} \cup \mathbf{c}'}$$

We denote this group by $P_{\mathbf{c} \cup \mathbf{c}'}^+$ because one could show (as in [Loi16, 3.2.9]) that it is the (unique because of simply connectedness assumption on G) maximal pro- p subgroup of the pointwise stabilizer in $G(K)$ of $\mathbf{c} \cup \mathbf{c}'$.

By Lemma 3.2.5, the subgroup Q_a contains the subgroup $P_{\mathbf{c} \cup \mathbf{c}'}^+$. Firstly, we prove that $P_{\mathbf{c} \cup \mathbf{c}'}^+$ is a normal subgroup of P . We can write $P = U_{a,\mathbf{c}} P_{\mathbf{c} \cup \mathbf{c}'}^+$. We have the following group inclusions:

- $[U_{a,\mathbf{c}}, U_{a,f_{\mathbf{c}}(a)^+}] \subset U_{a,f_{\mathbf{c}}(a)^+} \subset P_{\mathbf{c} \cup \mathbf{c}'}^+$ by Lemma 2.3.12 or commutativity according to whether the root a is multipliable or not;
- $[U_{a,\mathbf{c}}, T(K)_b^+] \subset U_{a,f_{\mathbf{c}}(a)^+} \subset P_{\mathbf{c} \cup \mathbf{c}'}^+$ by Lemma 2.3.4 or 2.2.1;
- $[U_{a,\mathbf{c}}, U_{-a,\mathbf{c}}] \subset U_{a,f_{\mathbf{c}}(a)^+} T(K)_b^+ U_{-a,f_{\mathbf{c}}(-a)^+} \subset P_{\mathbf{c} \cup \mathbf{c}'}^+$ by Lemma 2.3.6 or 2.2.2;
- $[U_{a,\mathbf{c}}, U_{b,\mathbf{c}}] \subset P_{\mathbf{c} \cup \mathbf{c}'}^+$ for any $b \in \Phi_{\text{nd}} \setminus \mathbb{R}a$ by quasi-concavity [BrT84, 4.5.10], as in proof of Lemma 3.2.5 (3).

Hence, $P_{\mathbf{c} \cup \mathbf{c}'}^+$ is a normal subgroup of P and the quotient $P/P_{\mathbf{c} \cup \mathbf{c}'}^+$ is isomorphic to $U_{a,f_{\mathbf{c}}(a)}/U_{a,f_{\mathbf{c}}(a)^+} = X_{a,f_{\mathbf{c}}(a)}$. Secondly, Q_a is a normal subgroup of P as the kernel of the action of P on $E_{\mathbf{c},a}$. Hence, the quotient group P/Q_a is a subgroup of $X_{a,f_{\mathbf{c}}(a)}$.

We define a subgroup Q'_a by $Q'_a = Q_a U_{2a,2f_{\mathbf{c}}(a)}$ if a is multipliable, L_a/L_{2a} is ramified and $f_{\mathbf{c}}(a) \in \Gamma'_a$; and by $Q'_a = Q_a$ otherwise. We show that the quotient group P/Q'_a can be endowed with a vector space structure.

Firstly, assume that a is non-multipliable or that L_a/L_{2a} is ramified. Then, by Proposition 3.1.11, we know that the quotient group $P/Q'_a = X_{a,f_{\mathbf{c}}(a)}$ is a κ_{L_a} -vector space (of dimension 1).

Secondly, assume that a is multipliable, that the extension L_a/L_{2a} is unramified and that $f'_{\mathbf{c}}(a) \notin \Gamma'_a$. Then, by Proposition 3.1.11, we know that $X_{a,f'_{\mathbf{c}}(a)} = X_{2a,2f'_{\mathbf{c}}(a)}$ is a $\kappa_{L_{2a}}$ -vector space of dimension 1 because the quotient space $X_{a,f'_{\mathbf{c}}(a)}/X_{2a,2f'_{\mathbf{c}}(a)}$ is zero by Lemma 3.1.13. Hence $P/Q'_a = X_{a,f'_{\mathbf{c}}(a)}$ is a vector space.

Finally, assume that a is multipliable, that L_a/L_{2a} is unramified and that $f'_{\mathbf{c}}(a) \in \Gamma'_a$. Then, by Proposition 3.1.11, we know that $P/Q'_a \simeq X_{a,f'_{\mathbf{c}}(a)}/X_{2a,2f'_{\mathbf{c}}(a)}$ is a κ_{L_a} -vector space of dimension 1.

As a consequence, on the one hand, the group P/Q'_a is commutative; hence $[P, P] \subset Q'_a$. On the other hand, the group P/Q'_a is of exponent p ; hence $P^p \subset Q'_a$. We get $P^p[P, P] \subset Q'_a$. Because $G(K)$ acts continuously on $X(G, K)$, the group Q_a is a closed subgroup of P as the kernel of the action of P on $E_{\mathbf{c},a}$. Moreover, the group $Q_a U_{2a,2f_{\mathbf{c}}(a)}$ is still closed. Hence $\text{Frat}(P) = \overline{P^p[P, P]} \subset Q'_a$.

If Φ is a reduced root system or if the extension L'/L_d is ramified, then for any root $a \in \Phi$ corresponding to a panel of \mathbf{c} , we get that $\text{Frat}(P)$ fixes $E_{\mathbf{c},a}$ pointwise and so it fixes the combinatorial ball of radius 1 centered in \mathbf{c} , denoted by $B(\mathbf{c}, 1)$, which is the union of all the $E_{\mathbf{c},a}$. By continuity of the action, the group $\text{Frat}(P) = \overline{P^p[P, P]}$ fixes pointwise the simplicial closure of $B(\mathbf{c}, 1)$. \square

3.2.6 Remark. Though the bounded torus $T(K)_b$ fixes pointwise the apartment A , its action on the 1-neighbourhood of this apartment is, in general, non-trivial. For instance, assume that Φ is a reduced root system and choose a spherical root $a \in \Phi$ directing a wall bordering the alcove \mathbf{c} . The action of $T(K)_b$ on $E_{\mathbf{c},a}$ corresponds to the action of a subgroup of $\kappa_{L_a}^{\times 2} \subset \kappa_{L_a}^{\times}$. The useful term of an element $t \in T(K)_b$ to describe its action on the set of alcoves $E_{\mathbf{c},a} \setminus \{\mathbf{c}'\}$ is $a(t)/\varpi_{L_a} \mathcal{O}_{L_a} \in \kappa_{L_a}^{\times 2}$. Indeed, let $\mathbf{c}'' \in E_{\mathbf{c},a} \setminus \{\mathbf{c}'\}$ and write it $\mathbf{c}'' = x_a(x) \cdot \mathbf{c}'$ where $\omega(x) = f'_{\mathbf{c}}(a)$. Then $t \cdot \mathbf{c}'' = tx_a(x)t^{-1} \cdot \mathbf{c}' = x_a(a(t)x) \cdot \mathbf{c}'$.

3.2.7 Corollary (of Proposition 3.2.2). *For any non divisible relative root $a \in \Phi_{\text{nd}}$,*

- *if $a \notin \Delta \cup \{-\theta\}$, we set $V_{a,\mathbf{c}} = U_{a,\mathbf{c}}$;*
- *if $a \in \Delta \cup \{-\theta\}$ is non-multipliable, we set $V_{a,\mathbf{c}} = U_{a,f_{\mathbf{c}}(a)^+}$;*
- *if $a \in \Delta \cup \{-\theta\}$ and if a is multipliable, and either L_a/L_{2a} is unramified or $f'_{\mathbf{c}}(a) \notin \Gamma'_a$, we set $V_{a,\mathbf{c}} = U_{a,f_{\mathbf{c}}(a)^+}$;*
- *if $a \in \Delta \cup \{-\theta\}$ and if a is multipliable, the extension L_a/L_{2a} is ramified and $f'_{\mathbf{c}}(a) \in \Gamma'_a$, we set $V_{a,\mathbf{c}} = U_{a,f_{\mathbf{c}}(a)^+} U_{2a,2f_{\mathbf{c}}(a)} = U_{a,f_{\mathbf{c}}(a)^+} U_{2a,\mathbf{c}}$.*

We have the following:

$$\text{Frat}(P) \leq \prod_{a \in \Phi_{\text{nd}}^-} V_{a,\mathbf{c}} \cdot T(K)_b^+ \cdot \prod_{a \in \Phi_{\text{nd}}^+} V_{a,\mathbf{c}} = T(K)_b^+ \prod_{a \in \Phi_{\text{nd}}} V_{a,\mathbf{c}}$$

Proof. Since $\text{Frat}(P) \subset P$, it suffices to check that $\text{Frat}(P) \cap U_a(K) \subset V_{a,\mathbf{c}}$ for any $a \in \Delta \cup \{-\theta\}$. Let $a \in \Delta \cup \{-\theta\}$. By Proposition 3.2.2, we have the inclusion $\text{Frat}(P) \subset Q_a U_{2a,\mathbf{c}}$ when a is multipliable, the extension L_a/L_{2a} is ramified and $f'_{\mathbf{c}}(a) \in \Gamma'_a$; we have the inclusion $\text{Frat}(P) \subset Q_a$ otherwise. In particular, $\text{Frat}(P) \cap U_a(K) \subset V_{a,\mathbf{c}}$. \square

3.2.8 Proposition. *We assume that Φ is a reduced root system. The group $Q = T(K)_b^+ \prod_{a \in \Phi} V_{a,\mathbf{c}}$ is the maximal pro- p subgroup of the pointwise stabilizer in $G(K)$ of $\text{cl}(B(\mathbf{c}, 1))$.*

Proof. Denote by $\text{cl}(B(\mathbf{c}, 1))$ the simplicial closure of the combinatorial ball of radius 1. Set $\Omega = \text{cl}(B(\mathbf{c}, 1)) \cap \mathbb{A}$. Denote by $\hat{P}_{B(\mathbf{c}, 1)}$ (resp. \hat{P}_{Ω}) the pointwise stabilizer in $G(K)$ of $\text{cl}(B(\mathbf{c}, 1))$ (resp. Ω). By [Lan96, 9.3 and 8.10], we can write $\hat{P}_{\Omega} = T(K)_b \prod_{a \in \Phi} U_{a,\Omega}$.

By Proposition 3.2.2, we get that Q fixes $\text{cl}(B(\mathbf{c}, 1))$ pointwise. Let $g \in \hat{P}_{B(\mathbf{c}, 1)} \subset \hat{P}_{\Omega}$. Write $g = t \prod_{a \in \Phi} u_a$ where $t \in T(K)_b$ and $u_a \in U_{a,\Omega} = V_{a,\mathbf{c}}$. By Lemma 3.2.5, we know that u_a fixes pointwise $\text{cl}(B(\mathbf{c}, 1))$.

Let $t \in T(K)_b$ fixing pointwise $\text{cl}(B(\mathbf{c}, 1))$. Let a be a root corresponding to a panel of \mathbf{c} . By Lemma 3.2.3, we write the orbit $E'_{\mathbf{c},a} = U_{a,\mathbf{c}\mathbf{c}'}$. For any $u \in U_{a,\mathbf{c}}$, the computation $u \cdot \mathbf{c}' = tu \cdot \mathbf{c}' = [t, u]u\mathbf{c}'$ shows that $[t, u] \in V_{a,\mathbf{c}}$. By Lemma 2.2.1, we get $a(t) \equiv 1 \pmod{\varpi}$.

Because this equality is true for any $a \in \Delta$, we get $t \in T' = \prod_{a \in \Delta} \tilde{a}(\pm 1 + \mathfrak{m}_{L_a})$. Hence $\hat{P}_{B(\mathbf{c}, 1)} \subset T' \prod_{a \in \Phi} V_{a,\mathbf{c}}$.

The index $[T' : T(K)_b^+]$ divides $\prod_{a \in \Delta} |\pm 1 + \mathfrak{m}_{L_a}/1 + \mathfrak{m}_{L_a}| = 2^{|\Delta|}$ which is prime to p since $p \neq 2$. Hence Q is a subgroup, which has an index prime to p , of the profinite group $\hat{P}_{B(\mathbf{c}, 1)}$. Since Q is a pro- p -group, we get that it is a maximal pro- p subgroup of $\hat{P}_{B(\mathbf{c}, 1)}$.

It remains to show that it is the only one, in other words that Q is normal in $\hat{P}_{B(\mathbf{c}, 1)}$. But since $T(K)_b$ normalises Q , this gives the result. \square

4 Computation in higher rank

As before, G is an almost- K -simple quasi-split simply-connected K -group and P is a maximal pro- p subgroup of $G(K)$. By a geometrical analysis, we provided, in Proposition 3.2.8, a description of the Frattini subgroup $\text{Frat}(P)$ as a subgroup of the (unique) maximal pro- p subgroup Q of a well-described stabilizer in $G(K)$. We now want to provide a large enough subset of $\text{Frat}(P)$,

so that this subset generates Q , and thus $\text{Frat}(P)$. We provide unipotent elements of $\text{Frat}(P)$ by finding some values $l_a \in \mathbb{R}$ with $a \in \Phi$ such that the valued root groups U_{a,l_a} are subgroups of $[P, P] \subset \text{Frat}(P)$. In the rank-1 case treated in Section 2, we have already found some values l_a . In higher rank, we can improve these values for most of roots; more precisely, for all roots which are not corresponding to panels of the (unique) alcove stabilized by P . In Section 4.1, we invert most of commutation relations providing bounds of valuations of root groups. In Section 4.2, we combine those inversions in the whole root system.

4.1 Commutation relations between root groups of a quasi-split group

We consider both the split semisimple \tilde{K} -group $\tilde{G} = G_{\tilde{K}}$ and the quasi-split K -group G . A **Chevalley-Steinberg system** of (G, \tilde{K}, K) is the datum of morphisms: $\tilde{x}_\alpha : \mathbb{G}_{a,\tilde{K}} \rightarrow \tilde{U}_\alpha$ parametrizing the various root groups of \tilde{G} , and satisfying some axioms of compatibility, given in [BrT84, 4.1.3], taking in account the commutation relations of absolute root groups and the $\text{Gal}(\tilde{K}/K)$ -action on root groups. Note that despite the morphisms parametrize root groups of \tilde{G} , a Chevalley-Steinberg system also depends on the quasi-split group G because of the relations between the \tilde{x}_α where $\alpha \in \tilde{\Phi}$. According to [BrT84, 4.1.3], a quasi-split group always admits a Chevalley-Steinberg system.

According to [Bor91, 14.5], there exist constants $(c_{r,s;\alpha,\beta})_{r,s \in \mathbb{N}^*; \alpha,\beta \in \tilde{\Phi}}$ in \tilde{K} , uniquely determined by the Chevalley-Steinberg system $(\tilde{x}_\alpha)_{\alpha \in \tilde{\Phi}}$, so that we have the following relations:

$$[\tilde{x}_\alpha(u), \tilde{x}_\beta(v)] = \prod_{r,s \in \mathbb{N}^*} \tilde{x}_{r\alpha+s\beta}(c_{r,s;\alpha,\beta} u^r v^s)$$

for any non-collinear roots $\alpha, \beta \in \tilde{\Phi}$ and any parameters $u, v \in \tilde{K}$. Moreover $c_{r,s;\alpha,\beta} = 0$ as soon as $r\alpha + s\beta \notin \tilde{\Phi}$ which makes the above products finite. These constants are called the **structure constants**. There is some flexibility in the choice of a Chevalley-Steinberg system, so that we can choose $c_{r,s;\alpha,\beta}$ in $\mathbb{Z}1_{\tilde{K}}$ where $1_{\tilde{K}}$ denotes the identity element of \tilde{K}^\times . More precisely, because \tilde{G} is generated by its root groups, it comes from a base change of a \mathbb{Z} -reductive group [SGA3, XXV 1.3]. In this case, one can determinate the $c_{r,s;\alpha,\beta}$, up to sign, to be some coefficients of a Cartan matrix [SGA3, XXIII 6.4]. More precisely, we have:

4.1.1 Lemma. *Let $\alpha, \beta \in \tilde{\Phi}$ be two (non-collinear) roots such that $\alpha + \beta \in \tilde{\Phi}$.*

If $\tilde{\Phi}$ is of type A_n, D_n , or E_n , then $c_{1,1;\alpha,\beta} \in \{\pm 1_{\tilde{K}}\}$.

If $\tilde{\Phi}$ is of type B_n, C_n , or F_4 , then $c_{1,1;\alpha,\beta} \in \{\pm 1_{\tilde{K}}, \pm 2 \cdot 1_{\tilde{K}}\}$.

If $\tilde{\Phi}$ is of type G_2 , then $c_{1,1;\alpha,\beta} \in \{\pm 1_{\tilde{K}}, \pm 2 \cdot 1_{\tilde{K}}, \pm 3 \cdot 1_{\tilde{K}}\}$.

In the quasi-split case, given two non-collinear relative roots $a, b \in \Phi$, there exist commutation relations between the corresponding root groups in terms of the parametrizations $(x_a)_{a \in \Phi}$. These commutation relations can be completely computed in the irreducible root system $\Phi(a, b) = \Phi \cap (\mathbb{R}a \oplus \mathbb{R}b)$ of rank 2. Hence $\Phi(a, b)$ is of type A_2, C_2, BC_2 or G_2 , and we can assume that a is shorter or has the same length as b . The various commutation relations are written down in [BrT84, Annexe A] where Bruhat and Tits consider the

angles between roots. Here, we follow another description in terms of length of roots, as in [PR84, §1].

We recall that, according to Section 2.1.2, the Galois group $\text{Gal}(\tilde{K}/K)$ acts on the absolute roots $\tilde{\Phi}$ and that the relative roots Φ can be seen as the orbits for this action. We recall that $d' = [L'/L_d]$ has been defined in 2.1.4 to be the number of absolute roots in a short root seen as an orbit. We do the following assumptions:

4.1.2 Hypothesis. We assume that the residue characteristic p of K is such that $p > d'$ and the following structure constants $c_{1,1;\alpha,\beta}$, where $\alpha, \beta \in \tilde{\Phi}$, are invertible in \mathcal{O}_K . In other words, this is to say that $p \geq 3$ if the relative root system Φ of the quasi-split almost- K -simple K -group G is of type B_n , C_n or F_4 ; and that $p \geq 5$ if Φ is of type G_2 .

4.1.3 Proposition. *Let $a, b, c \in \Phi$ be relative roots such that $c = a + b$ and, at least, one of the two roots a, b is non-multipliable. Let $l_a \in \Gamma_a$, $l_b \in \Gamma_b$ and $l_c \in \Gamma_c$ be values such that $l_c = l_b + l_a$.*

Let $u \in U_{c,l_c}$. If Hypothesis 4.1.2 is satisfied, then there exist elements $v \in U_{a,l_a}$, $v' \in U_{b,l_b}$ and $v'' \in \prod_{\substack{r,s \in \mathbb{N}^ \\ r+s \geq 2}} U_{ra+sb,rl_a+sl_b}$ such that $u = [v, v']v''$.*

Proof. If u is the identity element, the statement is clear. From now on, we assume that u is not the identity element. We choose $\alpha \in a$ and $\beta \in b$. In this proof, length of root is considered in the irreducible (possibly non-reduced) root system $\Phi(a, b)$ of rank 2.

In the below various cases, we always follow the same sketch of proof. Firstly, we recall the splitting field of the roots a , b and $c = a + b$ computed in Proposition 3.1.2. Secondly, we recall the commutation relation between U_a and U_b , provided by [BrT84, A.6] and we draw the relative roots that appear in the writing of this commutation relation. Thirdly, given a non-trivial unipotent element $u \in U_{c,l_c}$, we use the parametrisation of root groups, defined in Section 2.1.3, to provide suitable elements $v \in U_{a,l_a}$ and $v' \in U_{b,l_b}$. Finally, we check that $v'' = [v, v']^{-1}u$ is suitable.

Case $d' = 1$ or the relative roots a, b, c are long:

By Proposition 3.1.2, we have $L_a = L_b = L_c = L_d$.

By [BrT84, A.6], we have the following commutation relation:

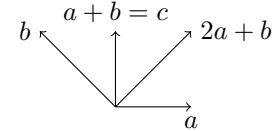

$$\forall y \in L_a, z \in L_b, [x_a(y), x_b(z)] = \prod_{r,s \in \mathbb{N}^*} x_{ra+sb}(c_{r,s;\alpha,\beta} y^r z^s)$$

There exists a parameter $x \in L_c$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. We choose $y \in L_a$ such that $\omega(y) = l_a$. This is possible because $l_a \in \Gamma_a = \Gamma_{L_a}$ by Lemma 2.1.12. We set $z = c_{1,1;\alpha,\beta}^{-1} xy^{-1} \in L_b$. Then $\omega(z) = \omega(x) - \omega(y) \geq l_c - l_a = l_b$ satisfies $x = c_{1,1;\alpha,\beta} yz$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and $(v'')^{-1} = \prod_{r,s \in \mathbb{N}^*, r+s \geq 2} x_{ra+sb}(c_{r,s;\alpha,\beta} y^r z^s)$. For any pair of non-negative integers (r, s) such that $r+s \geq 2$ and $ra+sb$ is a root, we get $\omega(c_{r,s;\alpha,\beta} y^r z^s) \geq r\omega(y) + s\omega(z) \geq rl_a + sl_b$. Hence $v'' \in \prod_{r,s \in \mathbb{N}^*, r+s \geq 2} U_{ra+sb,rl_a+sl_b}$. Thus $[v, v'] = u(v'')^{-1}$.

Case $d' = 2$, the roots a, c are short, b is long and non-divisible:

By Proposition 3.1.2, we have $L_b = L_{2a+b} = L_d$ and $L_a = L_c = L'$.

By [BrT84, A.6.b], there exist $\varepsilon_1, \varepsilon_2 \in \{\pm 1\}$ such that we have the following commutation relation:

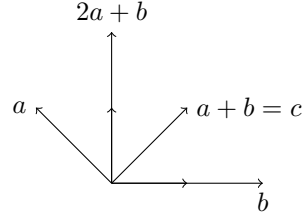

$$\forall y \in L_a, \forall z \in L_b, \quad \begin{bmatrix} x_a(y), x_b(z) \end{bmatrix} = \begin{matrix} x_{a+b}(\varepsilon_1 yz) \\ x_{2a+b}(\varepsilon_2 y^\tau yz) \end{matrix}$$

There exists a parameter $x \in L_c$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. We choose $z \in L_b$ such that $\omega(z) = l_b$. This is possible because $l_b \in \Gamma_b = \Gamma_{L_b}$. We set $y = \varepsilon_1 xz^{-1} \in L' = L_a$. Then $\omega(y) = \omega(x) - \omega(z) \geq l_c - l_b = l_a$ and $x = \varepsilon_1 yz$. The root $2a+b$ is non-divisible and we get $\omega(y^\tau yz) = 2\omega(y) + \omega(z) \geq 2l_a + l_b$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and $v'' = x_{2a+b}(-\varepsilon_2 y^\tau yz)$. Hence $v'' \in U_{2a+b, 2l_a+l_b}$. Thus $u = [v, v']v''$.

Case $d' = 2$, the roots a, c are short, b is long and divisible:

By Proposition 3.1.2, we have $L_a = L_c = L'$.

By [BrT84, A.6.c], there exist $\varepsilon_1, \varepsilon_2 \in \{\pm 1\}$ such that we have the following commutation relation:

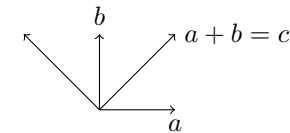

$$\forall y \in L_a, \forall z \in L_b^0, \quad \begin{bmatrix} x_a(y), x_{\frac{b}{2}}(0, z) \end{bmatrix} = \begin{matrix} x_{a+b}(\varepsilon_1 yz) \\ x_{a+\frac{b}{2}}(0, \varepsilon_2 y^\tau yz) \end{matrix}$$

There exists a parameter $x \in L_c$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. By Lemma 2.1.13, we have $l_b \in \Gamma_b = \omega(L'^{0 \times})$. Hence, we can choose $z \in L_b^0 = L^0$ such that $\omega(z) = l_b$. We set $y = \varepsilon_1 xz^{-1} \in L_a = L'$. Then $\omega(y) = \omega(x) - \omega(z) \geq l_c - l_b = l_a$ and $x = \varepsilon_1 yz$. The root $2a+b$ is divisible and we can check that $\omega(\varepsilon_2 y^\tau yz) = 2\omega(y) + \omega(z) \geq 2l_a + l_b$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and $v'' = x_{a+\frac{b}{2}}(0, -\varepsilon_2 y^\tau yz)$. Thus $u = [v, v']v''$.

Case $d' = 2$, the roots a, b are short, c is long and non-divisible:

By Proposition 3.1.2, we have $L_a = L_b = L'$ and $L_c = L_d$.

By [BrT84, A.6.b], there exists $\varepsilon \in \{\pm 1\}$ such that we have the following commutation relation:

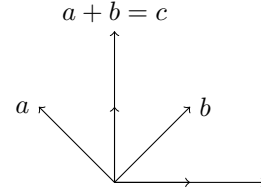

$$\forall y \in L_a, \forall z \in L_b, \quad \begin{bmatrix} x_a(y), x_b(z) \end{bmatrix} = x_{a+b}(\varepsilon(yz + {}^\tau y^\tau z))$$

There exists a parameter $x \in L_c$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. We choose $z \in L_b = L$ such that $\omega(z) = l_b$. This is possible because $l_b \in \Gamma_b$. We set $y = \frac{\varepsilon}{2} xz^{-1} \in L_a = L'$. This makes sense because p does not divide $d' = 2$, hence $2 \in \mathcal{O}_K^\times$. Then $\omega(y) = \omega(x) - \omega(z) \geq l_c - l_b = l_a$ and $\varepsilon \text{Tr}(yz) = \frac{x}{2} + \frac{{}^\tau x}{2} = x$ because $x \in L_d$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and $v'' = 1$. Thus $u = [v, v']v''$.

Case $d' = 2$, the roots a, b are short, c is long and divisible:

By Proposition 3.1.2, we have $L_a = L_b = L_{\frac{c}{2}} = L'$.

By [BrT84, A.6.c], there exists $\varepsilon \in \{\pm 1\}$ such that we have the following commutation relation:

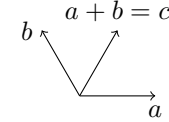

$$\forall y \in L_a, \forall z \in L_b, \quad \begin{bmatrix} x_a(y), x_b(z) \end{bmatrix} = x_{\frac{a+b}{2}} \left(0, \varepsilon(yz - {}^\tau y {}^\tau z) \right)$$

There exists a parameter $x \in L_{\frac{c}{2}}^0 = L'^0$ such that $u = x_{\frac{c}{2}}(0, x)$ and $\omega(x) \geq l_c$. We choose $z \in L_b = L'$ such that $\omega(z) = l_b$. This is possible because $l_b \in \Gamma_b$. We set $y = \frac{c}{2}xz^{-1} \in L_a = L'$. This is possible because p does not divide $d' = 2$, hence $2 \in \mathcal{O}_K^\times$. Then $\omega(y) = \omega(x) - \omega(z) \geq l_c - l_b = l_a$ and $\varepsilon(yz - {}^\tau y {}^\tau z) = \frac{x - {}^\tau x}{2} = x$ because $x + {}^\tau x = 0$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and $v'' = 1$. Thus $u = [v, v']v''$.

Case $d' = 2$, the roots a, b, c are short, a, b are non-multipliable:

By Proposition 3.1.2, we have $L_a = L_b = L_c = L'$.

By [BrT84, A.6.b], there exists $\varepsilon \in \{\pm 1\}$ such that we have the following commutation relation:

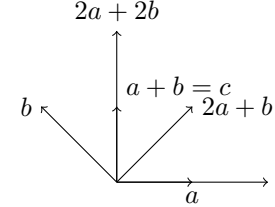

$$\forall y \in L_a, \forall z \in L_b, \quad \begin{bmatrix} x_a(y), x_b(z) \end{bmatrix} = x_{a+b}(\varepsilon yz)$$

There exists a parameter $x \in L_c$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. We choose $z \in L_b = L$ such that $\omega(z) = l_b$. We set $y = \varepsilon xz^{-1} \in L_a = L'$. Then $\omega(y) = \omega(x) - \omega(z) \geq l_c - l_b = l_a$ and $x = \varepsilon yz$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and $v'' = 1$. Thus $u = [v, v']v''$.

Case $d' = 2$, the roots a, b, c are short, b is non-multipliable and a is multipliable:

By Proposition 3.1.2, we have $L_a = L_b = L_c = L'$.

By [BrT84, A.6.c], there exist $\varepsilon_1, \varepsilon_2 \in \{\pm 1\}$ such that we have the following commutation relation:

$$\forall (y, y') \in H(L_a, L_{2a}), \forall z \in L_b, \quad \begin{bmatrix} x_a(y, y'), x_b(z) \end{bmatrix} = x_{a+b}(\varepsilon_1 yz, y' z {}^\tau z) x_{2a+b}(\varepsilon_2 z y')$$

There exists a parameter $(x, x') \in H(L_c, L_{2c})$ such that $u = x_c(x, x')$ and $\omega(x') \geq 2l_c$. We choose $z \in L_b$ such that $\omega(z) = l_b$. This is possible because $l_b \in \Gamma_b$. We set $y = \varepsilon_1 xz^{-1} \in L$ and $y' = x'z^{-1} {}^\tau z^{-1}$. Then $y {}^\tau y = y' + {}^\tau y'$ and $\omega(y') = \omega(x') - 2\omega(z) \geq 2l_c - 2l_b = 2l_a$. This implies $(y, y') \in H(L_a, L_{2a})_{l_a}$. Moreover $(x, x') = (\varepsilon_1 yz, y' z {}^\tau z)$. The root $2a + b$ is non-multipliable, non-divisible, and we can check that $\omega(\varepsilon_2 z y') = \omega(y') + \omega(z) \geq 2l_a + l_b$. Then, we set $v = x_a(y, y')$, $v' = x_b(z)$ and $v'' = x_{2a+b}(-\varepsilon_2 x' {}^\tau z^{-1})$. Thus $u = [v, v']v''$.

Case $d' = 2$, the roots a, b, c are short and a, b are multipliable:

This case where a and b are both multipliable is the only one excluded by the third assumption. It is considered in Remark 4.1.4.

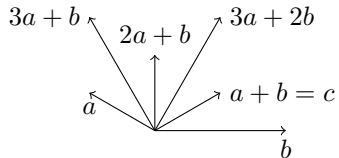

From now on, we assume $d' = 3$. This occurs only for the trialitarian D_4 .

Case $d' = 3$, the roots a, c are short and b is long:

By Proposition 3.1.2, we have $L_a = L_c = L_{2a+b} = L'$ and $L_b = L_{3a+b} = L_{3a+2b} = L_d$.

We denote by $\tau \in \Sigma_d$ an element representing an element of order 3 in the quotient group Σ_d/Σ_0 . For any $y \in L'$, we denote $\Theta(y) = {}^\tau y {}^{\tau^2} y$ and

$N(y) = y\Theta(y)$. By [BrT84, A.6.d], there exist an integer $\eta \in \{1, 2\}$ and four signs $\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4 \in \{-1, 1\}$ such that we have the following commutation relation:

$$\forall y \in L_a, \forall z \in L_b, \quad \begin{aligned} [x_a(y), x_b(z)] &= x_{a+b}(\varepsilon_1 yz) \\ &\quad x_{2a+b}(\varepsilon_2 \Theta(y)z) \\ &\quad x_{3a+b}(\varepsilon_3 N(y)z) \\ &\quad x_{3a+2b}(\varepsilon_4 \eta N(y)z^2) \end{aligned}$$

There exists a parameter $x \in L_c = L'$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. We choose $z \in L_b = L_d$ such that $\omega(z) = l_b$. This is possible because $l_b \in \Gamma_b$. We set $y = \varepsilon_1 xz^{-1} \in L_a = L'$. Then $\omega(y) = \omega(x) - \omega(z) \geq l_c - l_b = l_a$ and $x = \varepsilon_1 yz$. The root $2a + b$ is short and the parameter $\varepsilon_2 \Theta(y)z \in L'$ satisfies $\omega(\varepsilon_2^\tau y^{\tau^2} yz) = 2\omega(y) + \omega(z) \geq 2l_a + l_b$. The root $3a + b$ is long and the parameter $\varepsilon_3 N(y)z \in L_d$ satisfies $\omega(\varepsilon_3^\tau y^{\tau^2} yz) = 3\omega(y) + \omega(z) \geq 3l_a + l_b$. The root $3a + 2b$ is long and the parameter $\eta \varepsilon_4 z^2 N(y) \in L$ satisfies $\omega(\eta \varepsilon_4 z^2 y^\tau y^{\tau^2} y) = \omega(\eta) + 3\omega(y) + 2\omega(z) \geq 3l_a + 2l_b$.

Then we set $v = x_a(y)$, $v' = x_b(z)$ and

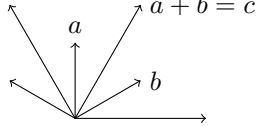

$$v'' = x_{3a+2b}(-\eta \varepsilon_4 N(y)z^2) x_{3a+b}(-\varepsilon_3 N(y)z) x_{2a+b}(-\varepsilon_2 \Theta(y)z)$$

Hence $v'' \in U_{2a+b, 2l_a+l_b} U_{3a+b, 3l_a+l_b} U_{3a+2b, 3l_a+2l_b}$. Thus $u = [v, v']v''$

Case $d' = 3$, the roots a, b are short and c is long:

By Proposition 3.1.2, we have $L_a = L_b = L'$ and $L_c = L_d$.

We denote by $\tau \in \Sigma_d$ an element representing an element of order 3 in the quotient group Σ_d/Σ_0 . For any $y \in L'$, we denote $\text{Tr}(y) = y + \tau y + \tau^2 y$. By [BrT84, A.6.d], there exists a sign $\varepsilon \in \{-1, 1\}$ such that:

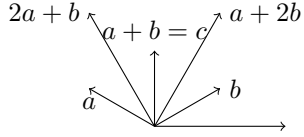

$$\forall y \in L_a, \forall z \in L_b, \quad [x_a(y), x_b(z)] = x_{a+b}(\varepsilon \text{Tr}(yz))$$

There exists a parameter $x \in L_c = L_d$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. We choose $z \in L_b = L'$ such that $\omega(z) = l_b$. This is possible because $l_b \in \Gamma_b$. We set $y = \frac{\varepsilon}{3} xz^{-1} \in L_a = L$. This is possible because p does not divide $3 = d'$, hence $3 \in \mathcal{O}_K^\times$. Then $\omega(y) = \omega(x) - \omega(z) \geq l_c - l_b = l_a$ and $x = \varepsilon \text{Tr}(yz)$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and $v'' = 1$. Thus $u = [v, v']v''$

Case $d' = 3$ and the roots a, b, c are short:

By Proposition 3.1.2, we have $L_a = L_b = L_c = L'$ and $L_{2a+b} = L_{a+2b} = L_d$.

We denote by $\tau \in \Sigma_d$ an element representing an element of order 3 in the quotient group Σ_d/Σ_0 . For any $y \in L'$, we denote $\Theta(y) = \tau y^{\tau^2} y \in L'$ and $\text{Tr}(y) = y + \tau y + \tau^2 y \in L_d$ and $N(y) = y\Theta(y) \in L_d$. For any $y, z \in L'$, we denote $(y * z) = \Theta(y + z) - \Theta(y) - \Theta(z) = \tau y^{\tau^2} z + \tau^2 y^\tau z$. By [BrT84, A.6.d], there exist three signs $\varepsilon_1, \varepsilon_2, \varepsilon_3 \in \{-1, 1\}$ such that we have the following commutation relation:

$$\forall y \in L_a, \forall z \in L_b, \quad \begin{aligned} [x_a(y), x_b(z)] &= x_{a+b}(\varepsilon_1 (y * z)) \\ &\quad x_{2a+b}(\varepsilon_2 \text{Tr}(\Theta(y)z)) \\ &\quad x_{a+2b}(\varepsilon_3 \text{Tr}(y\Theta(z))) \end{aligned}$$

We choose $z \in L_b = L'$ such that $\omega(z) = l_b$, this is possible because $l_b \in \Gamma_b$. Because p does not divide 2, hence $2 \in \mathcal{O}_K^\times$, we can set:

$$y = \frac{\varepsilon_1}{2} \cdot \frac{\text{Tr}(xz) - 2xz}{\Theta(z)} = \frac{\varepsilon_1}{2N(z)} (z\text{Tr}(xz) - 2xz^2)$$

so that $(y * z) = \varepsilon_1 x$. Indeed:

$$\begin{aligned} (y * z) &= \frac{\varepsilon_1}{2N(z)} (\tau z \text{Tr}(xz) - 2^\tau x^\tau z^2)^\tau z + \frac{\varepsilon_1}{2N(z)} (\tau^2 z \text{Tr}(xz) - 2^{\tau^2} x^{\tau^2} z^2)^\tau z \\ &= \frac{\varepsilon_1 \Theta(z)}{2N(z)} (\text{Tr}(xz) - 2^\tau x^\tau z + \text{Tr}(xz) - 2^{\tau^2} x^{\tau^2} z) \\ &= \frac{\varepsilon_1}{2z} (2xz) \end{aligned}$$

Then we have:

$$\begin{aligned} \omega(y) &= \omega(\text{Tr}(xz) - 2xz) - \omega(\Theta(z)) \\ &\geq \min(\omega(\text{Tr}(xz)), \omega(x) + \omega(z)) - 2\omega(z) \\ &\geq (\omega(x) + \omega(z)) - 2\omega(z) \\ &= \omega(x) - \omega(z) \\ &\geq l_c - l_a = l_b \end{aligned}$$

In fact, we get $\omega(y) = \omega(x) - \omega(z)$ because we deduce the inequality $\omega(x) \geq \omega(y) + \omega(z)$ from the formula $x = \varepsilon_1(y * z)$. The root $2a + b$ is long and we can check that the parameter $\varepsilon_2 \text{Tr}(\Theta(y)z) \in L_d$ satisfies $\omega(\varepsilon_2 \text{Tr}(\Theta(y)z)) \geq 2\omega(y) + \omega(z) = 2l_a + l_b$. The root $a + 2b$ is long and we can check that the parameter $\varepsilon_3 \text{Tr}(y\Theta(z)) \in L_d$ satisfies $\omega(\varepsilon_3 \text{Tr}(y\Theta(z))) \geq \omega(y) + 2\omega(z) = l_a + 2l_b$. Then, we set $v = x_a(y)$, $v' = x_b(z)$ and

$$v'' = x_{a+2b}(-\varepsilon_3 \text{Tr}(y\Theta(z))) x_{2a+b}(-\varepsilon_2 \text{Tr}(\Theta(y)z))$$

Hence $v'' \in U_{2a+b, 2l_a+l_b} U_{a+2b, l_a+2l_b}$. Thus $u = [v, v']v''$.

All the cases except the excluded one, where a, b both are multipliable, have been treated. \square

4.1.4 Remark. In the excluded case, by [BrT84, A.6.c], there exists a sign $\varepsilon \in \{\pm 1\}$ such that we have the following commutation relation:

$$\begin{aligned} \forall(y, y') &\in H(L_a, L_{2a}), \\ \forall(z, z') &\in H(L_b, L_{2b}), \\ [x_a(y, y'), x_b(z, z')] &= x_{a+b}(\varepsilon yz) \end{aligned}$$

There exists a parameter $x \in L_c = L'$ such that $u = x_c(x)$ and $\omega(x) \geq l_c$. The problem is that, for a multipliable root $a \in \Phi$, the set of values Γ_a does not control completely the valuation of the first term y of a parameter $(y, y') \in H(L_a, L_{2a})$. One can show that, when $l_a \notin \Gamma'_a$, we get $\omega(y) > l_a$. Hence the inclusion $[U_{a, l_a}, U_{b, l_b}] \subset U_{a+b, l_a+l_b}$ is not, in general, an equality.

4.2 Generation of unipotent elements thanks to commutation relations between valued root groups

In Corollary 3.2.7, we obtained that $\text{Frat}(P)$ is a subgroup of a pro- p group Q written in terms of valued root groups. We want to get an equality when it is possible. It suffices to provide a generating system of the biggest group consisting of p -powers and commutators of elements chosen in P . In a general

consideration of a compact open subgroup H of $G(K)$, in Section 4.2.1, we do an induction on the positive roots from the highest to the simple roots to provide bounds of valued root groups contained in $[H, H]$; in Section 4.2.2, we furthermore consider the length of roots to provide bounds for the whole root system. In Section 4.2.3, we go back to the situation of the Frattini subgroup $\text{Frat}(P) = \overline{P^p[P, P]} \supset [P, P]$.

In order to do an induction on the set of relative roots, the following lemma in Lie combinatorics explains how to get, step by step, all the roots as a linear combination with integer coefficients of the lowest root and the simple roots.

4.2.1 Lemma. *Let Φ be an irreducible root system of rank greater or equal to 2 and Δ be a basis of simple roots in Φ , associated to an order Φ^+ . Let h be the highest root for this order.*

- (1) *Let $\beta \in \Phi^+ \setminus (\Delta \cup 2\Delta)$ be a positive root which is not the multiple of a simple root. Then, there exists a simple root $\alpha \in \Delta$ and a positive root $\beta' \in \Phi^+$ such that $\beta = \alpha + \beta'$ and the roots α, β' are not collinear.*
- (2) *Let $\gamma \in \Phi^- \setminus \{-h\}$. There exists a positive root $\beta \in \Phi^+$ and a negative root $\gamma' \in \Phi^-$ such that $\gamma = \beta + \gamma'$ and the roots β, γ' are not collinear.*
- (3) *Let $\alpha \in \Delta$. There exists a simple root $\beta \in \Delta$ such that $\alpha + \beta$ is a positive root. Moreover, the roots $\alpha + \beta \in \Phi^+$ and $-\beta$ are not collinear.*

Proof. According to notations of [Bou81, VI.1.3], we denote by V the \mathbb{R} -vector space generated by Δ containing Φ and by $(\cdot|\cdot)$ a scalar product which is invariant by the Weyl group.

(1) Let $\beta \in \Phi^+ \setminus \Delta$ be a positive non-simple root. Because Δ is a basis of the Euclidean vector space V and $\beta \in \Phi^+$ is in the cone $\mathbb{Z}_{>0}\Delta$ generated by Δ , there exists $\alpha \in \Delta$ such that $(\alpha|\beta) > 0$. By [Bou81, VI.1.3 Corollaire], we get $\beta' = \beta - \alpha \in \Phi$ because we excluded the case where $\alpha = \beta$ assuming $\beta \notin \Delta$. Moreover, β' is a positive root because its integer coefficients when we write it in the basis Δ all have the same sign (hence are positive). Finally, β' and α are not collinear because we assumed that β is not the multiple of a simple root. Hence $\beta' = \beta - \alpha$ satisfies assertion (1).

(2) Let $\gamma \in \Phi^- \setminus \{-h, -\frac{h}{2}\}$. If $(-h|\gamma) > 0$, then the sum $\beta = h + \gamma \in \Phi^+$ is a positive root. Moreover, $-h$ and β are not collinear because we assumed that γ and h are not collinear. Hence β and $\gamma' = -h$ satisfies assertion (2). Otherwise, we necessarily get the equality $(-h|\gamma) = 0$ according to [Bou81, VI.1.8 Proposition 25] and there exists a simple root $\alpha \in \Delta$ such that $(\alpha|\gamma) > 0$, because the roots $\alpha \in \Delta$ form a basis of the Euclidean space V and $-h \neq 0$. The roots γ and α are not collinear because, if they were, we should have $\gamma \in \mathbb{R}_+\alpha$ according to assumption $(\gamma|\alpha) > 0$; and this contradicts $\gamma \in \Phi^-$. Hence $\gamma' = \gamma - \alpha \in \Phi^-$ is a negative root. Thus, γ' and $\beta = \alpha$ satisfies assertion (2).

Let $\gamma = -\frac{h}{2}$. In particular, this happens only if Φ is non-reduced. We can apply the same method inside Φ_{nd} , because the root $-\frac{h}{2}$ is a short root of Φ_{nd} , hence it cannot be collinear to the highest root of Φ_{nd} .

(3) Let $\alpha \in \Delta$. Any β connected to α by an edge in $\text{Dyn}(\Delta)$ satisfies (3). Such a simple root exists because we assumed Φ to be of rank greater of equal to 2. \square

4.2.2 Lemma. *Let Φ be an irreducible root system of rank greater or equal to 2 and Δ be a basis of simple roots in Φ , associated to an order Φ^+ . Let h*

be the highest root for this order. For any root $\gamma \in \Phi$, there exist non-negative integers $(n_\alpha(\gamma))_{\alpha \in \Delta}$ such that:

$$\gamma = -h + \sum_{\alpha \in \Delta} n_\alpha(\gamma) \alpha$$

Proof. We proceed by induction on height. If $\gamma = -h$, it is clear.

Induction step: If $\gamma \in \Phi$, by 4.2.1, there exists $\beta \in \Phi^+$ and $\gamma' \in \Phi$ such that $\gamma = \gamma' + \beta$. Hence by induction hypothesis, there exist non-negative integers $(n_\alpha(\gamma'))$ such that $\gamma' = -h + \sum_{\alpha \in \Delta} n_\alpha(\gamma') \alpha$. According to [Bou81, VI.1.6 Théorème 3], there exist non-negative integers $(n_\alpha(\beta))$ such that $\beta = \sum_{\alpha \in \Delta} n_\alpha(\beta) \alpha$. Hence, the property is satisfied by $n_\alpha(\gamma) = n_\alpha(\gamma') + n_\alpha(\beta)$. \square

4.2.3 Definition. Let $f : \Phi \rightarrow \mathbb{R}$ be a map. We say that the map f is **concave** if it satisfies the following axioms:

- (C0) $f(2a) \leq 2f(a)$ for any root $a \in \Phi$ such that $2a \in \Phi$;
- (C1) $f(a+b) \leq f(a) + f(b)$ for any roots $a, b \in \Phi$ such that $a+b \in \Phi$;
- (C2) $0 \leq f(a) + f(-a)$ for any root $a \in \Phi$.

Despite these axioms look like a convexity property, they correspond in fact to a concavity property in terms of valued root groups.

4.2.4 Example. For any non-empty subset $\Omega \subset \mathbb{A}$, the map $f_\Omega : a \mapsto \sup\{-a(x), x \in \Omega\}$ is concave. Later, we will apply Propositions 4.2.6 and 4.2.9 to values $l_a = f_{\mathbf{c}_{\text{af}}}(a)$.

4.2.1 Lower bounds for positive root groups

Let $(l_a)_{a \in \Phi}$ be any values in \mathbb{R} . We define the following values $(l'_b)_{b \in \Phi^+}$ depending on the l_a , to become bounds for the positive root groups.

4.2.5 Notation. For any positive root $b \in \Phi^+$, we can write uniquely $b = \sum_{\alpha \in \Delta} n_\alpha(b) \alpha$ where $n_\alpha(b) \in \mathbb{N}$ are nonnegative integers (not all equal to zero). We define a value $l'_b = \sum_{\alpha \in \Delta} n_\alpha(b) l_\alpha$.

Thanks to Lemma 4.2.1, we do several inductions on various root systems to provide bounds, thanks to Proposition 4.1.3, for the valuations of the valued root groups contained in the Frattini subgroup $\text{Frat}(P)$. The first step, in terms of positive roots, is the following:

4.2.6 Proposition. Let $(l_a)_{a \in \Phi}$ be values in \mathbb{R} . Assume that for any simple root $a \in \Delta$, we have $l_a \in \Gamma_a$.

- (1) Then $l'_b \in \Gamma_b$ for any positive root $b \in \Phi^+$.
- (2) Assume, moreover, that the map $a \mapsto l_a$ is concave. Then we have $l'_b \geq l_b$ for any positive root $b \in \Phi^+$.
- (3) Furthermore, assume that Hypothesis 4.1.2 is satisfied. Let H be a (compact open) subgroup of $G(K)$ containing the valued root groups U_{a, l_a} for $a \in \Phi$. Then for any root $b \in \Phi^+ \setminus \Delta$, the derived group $[H, H]$ contains the valued root group U_{b, l'_b} .

Proof. (1) We apply Proposition 3.1.2 and Lemmas 2.1.13 and 2.1.12 in the various cases.

First case: Φ is a reduced root system and L'/L_d is unramified. For any root $b \in \Phi^+$, the set of values Γ_b of b is $\Gamma_{L'} = \Gamma_{L_d}$. Hence, the sum $l'_b = \sum_{\alpha \in \Delta} n_\alpha(b) l_\alpha$ is an element of $\Gamma_{L_d} = \Gamma_b$.

Second case: Φ is a reduced root system and L'/L_d is ramified.

For any long root of Φ , its set of values is the group $d'\Gamma_{L'} = \Gamma_{L_d}$. For any short root of Φ , its set of values is the group $\Gamma_{L'}$. Hence, for any short root $b \in \Phi$, the sum $l'_b = \sum_{\alpha \in \Delta} n_\alpha(b)l_\alpha$ is an element of $\Gamma_{L'} = \Gamma_b$.

Let $b \in \Phi$ be a long relative root arising from an absolute root $\beta \in \tilde{\Phi}$. Write $\beta = \sum_{\tilde{\alpha} \in \tilde{\Delta}} n'_{\tilde{\alpha}}(\beta)\tilde{\alpha}$. Hence $n_\alpha(b) = \sum_{\tilde{\alpha} \in \alpha} n'_{\tilde{\alpha}}(\beta)$. Moreover, $n'_{\tilde{\alpha}}(\beta)$ is constant along the class α because β is Σ_d -invariant and $\alpha = \Sigma_d \cdot \tilde{\alpha}$ is an orbit. Hence, for any short simple root α arising from $\tilde{\alpha}$ taking in the same irreducible component as β , we obtain $n_\alpha(b) = d'n'_{\tilde{\alpha}}(\beta)$. As a consequence, $n_\alpha(b)l_\alpha = n'_{\tilde{\alpha}}(\beta)d'l_\alpha \in d'\Gamma_{L'} = \Gamma_{L_d}$. For any long simple root α , we have $l_\alpha \in \Gamma_{L_d}$. Hence, the sum $l'_b = \sum_{\alpha \in \Delta} n_\alpha(b)l_\alpha$ is an element of $\Gamma_{L_d} = \Gamma_b$.

Third case: Φ is a non-reduced root system. The set of values of any multipliable root is $\frac{1}{2}\Gamma_{L'}$. The set of values of any non-multipliable, non-divisible root is $\Gamma_{L'}$. For any multipliable root $b \in \Phi^+$, the sum l'_b is an element of $\frac{1}{2}\Gamma_{L'} = \Gamma_b$. We number by a_1, \dots, a_{l-1} the non-multipliable simple roots and by a_l the multipliable simple root. Any non-multipliable non-divisible root $b \in \Phi^+$ can be written as $b = \sum_{j=1}^l n_j(b)a_j$ with $n_l \in \{0, 2\}$. We have $n_j(b)l_{a_j} \in \Gamma_{a_j} = \Gamma_L$ and $n_l(b)l_{a_l} \in 2\Gamma_{a_l} = \Gamma_{L'}$. Hence the sum l'_b is an element of $\Gamma_{L'} = \Gamma_b$.

(2) For any positive root $b \in \Phi^+$, we apply recursively Lemma 4.2.1(1) to Φ^+ in order to write $b = \sum_{j=1}^N a_j$ where $a_j \in \Delta$ are simple roots (possibly with repetitions) and $N \in \mathbb{N}^*$ such that $b_n = \sum_{j=1}^n a_j$ is a (positive) root for any $n \in [1, N]$. By induction, we get that $l'_{b_n} \geq l_{b_n}$. Indeed, for any $0 \leq n \leq N-1$, we have $l'_{b_{n+1}} = l'_{b_n} + l_{a_{n+1}} \geq l_{b_n} + l_{a_{n+1}}$ by induction hypothesis; and from the concavity relation (C1), we end the inequality by $l_{b_n} + l_{a_{n+1}} \geq l_{b_n + a_{n+1}} = l_{b_{n+1}}$. Hence, we obtain the inequality $l_b \leq l'_b$.

(3) Consequently, we have the inclusion $U_{b, l'_b} \subset U_{b, l_b}$. We proceed by decreasing strong induction on height in the root system Φ relatively to the basis Δ .

Basis: Let h be the highest root of Φ . For the root group U_{h, l'_h} , we know by Lemma 4.2.1(1) that there exists a simple root $a \in \Delta$ and a positive root $b \in \Phi^+$ non-collinear to a , and non both multipliable, such that $h = a + b$. Let $u \in U_{h, l'_h}$. We have the group inclusion $U_{b, l'_b} \subset U_{b, l_b}$. We know by Proposition 4.1.3, that there exist elements $v \in U_{a, l_a}$, $v' \in U_{b, l'_b}$ and $v'' \in \prod_{r, s \in \mathbb{N}^*; r+s \geq 2} U_{ra+sb, rl_a+sl'_b}$ such that $u = [v, v']v''$. But, for any pair of positive integers (r, s) such that $r + s \geq 2$, the character $ra + sb$ is not a root because this would contradict maximality of height of h . Hence $v'' = 1$. Thus, we get $U_{h, l'_h} \subset [H, H]$.

Inductive step: Let $c \in \Phi^+ \setminus \Delta$. By Lemma 4.2.1(1), we write $c = a + b$ where $a \in \Delta$ and $b \in \Phi^+$. Let $u \in U_{c, l'_c}$. We know by Proposition 4.1.3, that there exist elements $v \in U_{a, l_a}$, $v' \in U_{b, l'_b}$ and $v'' \in \prod_{r, s \in \mathbb{N}^*; r+s \geq 2} U_{ra+sb, rl_a+sl'_b}$ such that $u = [v, v']v''$. For any pair of positive integers (r, s) such that $r + s \geq 2$, if the character $ra + sb$ is a root, then we have $rl_a + sl'_b = l'_{ra+sb}$ by definition of the l' . Moreover, the height of $ra + sb$ is greater than c . By induction hypothesis, the valued root group $U_{ra+sb, l'_{ra+sb}}$ is a subgroup of $[H, H]$, hence $v'' \in [H, H]$. As a consequence, we get $U_{c, l'_c} \subset [H, H]$. \square

4.2.2 Lower bounds for negative root groups

In order to get an analogous result for negative roots, doing an induction on height no longer works. In fact, we have to consider length of roots instead

of height. We recall that, in Notation 3.1.4, we defined a pure Lie theoretic dual root system Φ^D .

4.2.7 Lemma. *Let Φ be a reduced irreducible non-simply laced root system of rank $l \geq 2$. Let Φ^+ be an ordering on Φ and $\theta \in \Phi$ be the short root such that θ^D is the highest root of Φ^D in the corresponding ordering. Then, any short root $c \in \Phi \setminus \{-\theta\}$ can be written $c = a + b$ where $a, b \in \Phi$ are non-collinear roots such that $a \in \Phi$ is short and $b \in \Phi^+$. In particular, every short root is higher than $-\theta$.*

Proof. We provide these roots case by case thanks to an explicit realization of the root system in \mathbb{R}^l . Let $(e_i)_{1 \leq i \leq l}$ be the canonical basis of the Euclidean space \mathbb{R}^l .

Φ is of type B_l with $l \geq 2$:

Basis: $a_i = e_i - e_{i+1}$ where $1 \leq i < l$ and $a_l = e_l$

Short roots: $\pm e_i$ for $1 \leq i \leq l$ and $\theta = e_1$

For any short root $c \in \Phi \setminus \{-\theta\}$,

- if $c \in \Phi^+$, we write $c = e_i = a + b$ with $1 \leq i \leq l$, $a = -e_j$, $b = e_i + e_j$ and $j \neq i$;
- if $c \in \Phi^-$, we write $c = -e_i = a + b$ with $1 < i \leq l$, $a = -e_1$ and $b = e_1 - e_i$.

Φ is of type C_l with $l \geq 3$:

Basis: $a_i = e_i - e_{i+1}$ where $1 \leq i < l$ and $a_l = 2e_l$

Short roots: $\pm e_i \pm e_j$ where $1 \leq i < j \leq l$ and $\theta = e_1 + e_2$

For any short root $c \in \Phi \setminus \{-\theta\}$,

- if $c = e_i \pm e_j$ where $1 \leq i < j \leq l$, we write $c = a + b$ where $a = -e_i \pm e_j$ and $b = 2e_i$;
- if $c = -e_i \pm e_j$ where $1 < i < j \leq l$, we write $c = a + b$ where $a = -e_1 - e_i$ and $b = e_1 \pm e_i$;
- if $c = -e_1 \pm e_j$ where $2 < j \leq l$, we write $c = a + b$ where $a = -e_1 - e_2$ and $b = e_2 \pm e_j$;
- if $c = -e_1 + e_2$, we write $c = a + b$ where $a = -e_1 - e_3$ and $b = e_2 + e_3$.

Φ is of type F_4 :

Basis: $a_1 = e_2 - e_3$, $a_2 = e_3 - e_4$, $a_3 = e_4$ and $a_4 = \frac{1}{2}(e_1 - e_2 - e_3 - e_4)$

Highest root: $h = e_1 + e_2 = 2a_1 + 3a_2 + 4a_3 + 2a_4$

Short roots: $\pm e_i$ where $1 \leq i \leq 4$ and $\frac{1}{2}(\pm e_1 \pm e_2 \pm e_3 \pm e_4)$ and $\theta = e_1$

For any short root $c \in \Phi \setminus \{-\theta\}$,

- if $c = e_1$, we write $c = a + b$ where $a = \frac{1}{2}(e_1 - e_2 - e_3 - e_4)$ and $b = \frac{1}{2}(e_1 + e_2 + e_3 + e_4)$;
- if $c = \pm e_i$ where $1 < i \leq 4$, we write $c = a + b$ where $a = \frac{1}{2}(-e_1 + \pm e_i - e_j - e_k)$ and $b = \frac{1}{2}(e_1 + \pm e_i + e_j + e_k)$ where $\{i, j, k\} = \{2, 3, 4\}$;
- if $c = \frac{1}{2}(e_1 \pm e_2 \pm e_3 \pm e_4)$, we write $c = a + b$ where $a = \frac{1}{2}(-e_1 \mp e_2 \pm e_3 \pm e_4)$ et $b = e_1 \pm e_2$;
- if $c = \frac{1}{2}(-e_1 \pm e_2 \pm e_3 \pm e_4)$, we write $c = a + b$ where $a = -e_1$ and $b = \frac{1}{2}(e_1 \pm e_2 \pm e_3 \pm e_4)$.

Φ is of type G_2 :

Basis: α, β where α is short and β is long

Highest root: $h = 3\alpha + 2\beta$

We have $\theta = 2\alpha + \beta$. We summarize the choices for the short roots, except $-\theta$, case by case, in the following table:

c	$2\alpha + \beta$	$\alpha + \beta$	α	$-\alpha$	$-\alpha - \beta$
a	α	$-\alpha$	$-\alpha - \beta$	$-2\alpha - \beta$	$-2\alpha - \beta$
b	$\alpha + \beta$	$2\alpha + \beta$	$2\alpha + \beta$	$\alpha + \beta$	α

□

We let $(\delta_c)_{c \in \Phi}$, Φ_{nd}^δ , θ and h be defined as in Notation 3.1.6. Let $(l_a)_{a \in \Phi}$ be any values in \mathbb{R} . We define the following values $(l_c'')_{c \in \Phi}$ depending on the l_a , to become bounds for all the root groups.

4.2.8 Notation. For any non-divisible root $c \in \Phi_{\text{nd}}$, thanks to Lemma 4.2.2 applied in the root system Φ_{nd}^δ , we write:

$$c^\delta = -\theta^\delta + \sum_{\alpha^\delta \in \Delta^\delta} n'_\alpha(c) \alpha^\delta \in \Phi^\delta$$

with $n'_\alpha(c) \in \mathbb{N}$. We define $l_c'' \in \mathbb{R}$ by:

$$\delta_c l_c'' = \delta_{-\theta} l_{-\theta} + \sum_{\alpha \in \Delta} \delta_\alpha n'_\alpha(c) l_\alpha$$

Furthermore, for any multipliable root $c \in \Phi$, we define $l_{2c}'' = 2l_c''$. Note that for any root $c \in \Phi$, there exist integers $n_\alpha(c)$ for $\alpha \in \Delta$, uniquely determined by:

$$c = \sum_{\alpha \in \Delta} n_\alpha(c) \alpha$$

This extends Notation 4.2.5.

These values overestimate the values of valued root groups contained in the derived group $[H, H]$. In particular, this proposition provides values even for simple roots, which were not treated in Proposition 4.2.6. We can remark on an example that, in general, this values are not optimal for positive non-simple roots.

4.2.9 Proposition. *Let $(l_a)_{a \in \Phi}$ be values in \mathbb{R} . Assume that for any simple root $a \in \Delta$, we have $l_a \in \Gamma_a$ and that $l_{-\theta} \in \Gamma_{-\theta}$.*

- (1) *We have $l_c'' \in \Gamma_c$ for any non-divisible root $c \in \Phi_{\text{nd}} \setminus \{-\theta\}$.*
- (2) *We assume, moreover, that the map $a \mapsto l_a$ is concave. For any root $c \in \Phi$, we have $l_c'' \geq l_c$; for any positive root $b \in \Phi^+$, we have $l_b'' \geq l_b' \geq l_b$.*
- (3) *We assume, moreover, that the irreducible root system Φ is not of rank 1 and that Hypothesis 4.1.2 is satisfied. Let H be a (compact open) subgroup of $G(K)$ containing the valued root groups U_{a, l_a} for $a \in \Phi$. If G is a triality D_4 (i.e. Φ of type G_2 and $\delta_\theta = 3$), we assume furthermore that $l'_\theta + l_{-\theta} \leq \omega(\varpi_{L'})$. Then the derived group $[H, H]$ contains the valued root groups $U_{c, l_c''}$ for any root $c \in \Phi \setminus \{-\theta\}$.*

Proof. (1) If Φ is a reduced root system, then $\Phi^\delta = \Phi$ if the extension L'/L_d is unramified; and $\Phi^\delta = \Phi^D$ if the extension L'/L_d is ramified. By Definition 3.1.5, for any root $c \in \Phi$, the integer δ_c is the order of the quotient group Γ_c/Γ_{L_d} , so that $\delta_c \Gamma_c = \Gamma_{L_d}$. Hence, each term $n'_\alpha(c) \delta_\alpha l_\alpha$ and $\delta_{-\theta} l_{-\theta}$ of the sum belongs to the group Γ_{L_d} . Thus $\delta_c l_c'' \in \Gamma_{L_d} = \delta_c \Gamma_c$, and we obtain $l_c'' \in \Gamma_c$ for any root $c \in \Phi$.

If Φ is a non-reduced root system, then the set of values of multipliable roots is $\frac{1}{2}\Gamma_{L'}$ by Lemma 2.1.13 and the set of values of non-multipliable and non-divisible roots is $\Gamma_{L'}$. For any non-divisible root $c \in \Phi$, the value $\delta_c l_c$ is an element of $\Gamma_{L'}$, hence so is the sum l_c'' . If c is non-multipliable, then $\delta_c = 1$, hence $l_c'' \in \Gamma_{L'} = \Gamma_c$. If c is multipliable, then $\delta_c = 2$ hence $l_c'' \in \frac{1}{2}\Gamma_{L'} = \Gamma_c$.

(2) In the following, for any root $c \in \Phi_{\text{nd}}$, we denote by $n_\alpha(c)$ and $n'_\alpha(c)$ the integers defined in Notation 4.2.8. We furthermore denote by $n_\alpha^\delta(c)$ the integers uniquely determined by the following writing in basis Δ^δ : $c^\delta = \sum_{\alpha \in \Delta} n_\alpha^\delta(c) \alpha^\delta$. From uniqueness, for any $\alpha \in \Delta$, we deduce that $\delta_\alpha n_\alpha^\delta(c) = \delta_c n_\alpha(c)$ and that $n'_\alpha(c) = n_\alpha^\delta(\theta) - n_\alpha^\delta(c) \geq 0$ (it is a non-negative integer).

Let $b \in \Phi_{\text{nd}}^+$ be a non-divisible positive root. In $V^* = \text{Vect}(\Phi)$ we have:

$$\begin{aligned} b^\delta &= -\theta^\delta + \theta^\delta + \sum_{\alpha \in \Delta} n_\alpha^\delta(b) \alpha^\delta \\ &= -\theta^\delta + \sum_{\alpha \in \Delta} (n_\alpha^\delta(\theta) + n_\alpha^\delta(b)) \alpha^\delta \end{aligned}$$

By definition of l_b'', l_b', l_θ' , we get:

$$\begin{aligned} \delta_b l_b'' &= \delta_\theta l_{-\theta} + \sum_{\alpha \in \Delta} (n_\alpha^\delta(b) + n_\alpha^\delta(\theta)) \delta_\alpha l_\alpha \\ &= \delta_\theta l_{-\theta} + \left(\sum_{\alpha \in \Delta} \delta_b n_\alpha(b) l_\alpha \right) + \left(\sum_{\alpha \in \Delta} \delta_\theta n_\alpha(\theta) l_\alpha \right) \\ &= \delta_\theta l_{-\theta} + \delta_b l_b' + \delta_\theta l_\theta' \end{aligned}$$

Hence $\delta_b(l_b'' - l_b') = \delta_\theta(l_\theta' + l_{-\theta})$. According to Proposition 4.2.6(2), we have $l_b' \geq l_b$ for all positive roots and, in particular, $l_\theta' \geq l_\theta$. Hence, by axiom (C2), we get $l_\theta' + l_{-\theta} \geq l_\theta + l_{-\theta} \geq 0$. As a consequence, we get $l_b'' \geq l_b' \geq l_b$.

Let $b \in \Phi^+$ be a multipliable root. Then $l_{2b}'' = 2l_b'' \geq l_{2b}' = 2l_b' \geq 2l_b$. By axiom (C0), we have $2l_b \geq l_{2b}$, hence $l_{2b}'' \geq l_{2b}$.

Let $c \in \Phi_{\text{nd}}^-$ be a non-divisible negative root. We want to prove that $l_c'' \geq l_c$. We proceed by induction on height in Φ_{nd} .

• **First case:** $\Phi_{\text{nd}}^\delta = \Phi_{\text{nd}}$. Then $\delta_\theta = 1$, $h = \theta$ and $\delta_c = 1$ for any root $c \in \Phi$. By definition, $l_{-h}'' = l_{-\theta}' = l_{-\theta} = l_{-h}$.

If $c \neq -\theta$, by Lemma 4.2.1(2), there exist $a \in \Phi_{\text{nd}}$ and $b \in \Phi_{\text{nd}}^+$ such that $c = a + b$. From $c = -\theta + \sum_\alpha n'_\alpha(c) \alpha = -\theta + \sum_\alpha n'_\alpha(a) \alpha + \sum_\alpha n_\alpha(b) \alpha = a + b$, we deduce $n'_\alpha(c) = n'_\alpha(a) + n_\alpha(b)$. Hence $l_c'' = l_a'' + l_b' \geq l_a + l_b'$ by induction hypothesis. By axiom (C1) and because $l_b' \geq l_b$, we get $l_c'' \geq l_a + l_b \geq l_{a+b} = l_c$.

• **Second case:** $\Phi_{\text{nd}}^\delta = \Phi_{\text{nd}}^D \neq \Phi_{\text{nd}}$. Then $\delta_\theta = d'$.

We firstly do the induction, initialized by $l_{-\theta}'' = l_{-\theta}$, on height of short roots. Assume that $c \neq -\theta$ is a short root in Φ_{nd} . By Lemma 4.2.7, there exist a short root $a \in \Phi_{\text{nd}}$ and a positive root $b \in \Phi_{\text{nd}}^+$ such that $c = a + b$. Hence $\delta_a = \delta_c = \delta_\theta$. We have $\delta_\theta b = \delta_\theta(c - a) = c^\delta - a^\delta = -\theta^\delta + \sum_\alpha \delta_\alpha n'_\alpha(c) + \theta^\delta - \sum_\alpha \delta_\alpha n'_\alpha(a) = \sum_\alpha \delta_\alpha (n'_\alpha(c) - n'_\alpha(a))$. Hence $\delta_\theta n_\alpha(b) = \delta_\alpha (n'_\alpha(c) - n'_\alpha(a))$ for any $\alpha \in \Delta$. Hence, we get:

$$\begin{aligned} \delta_c l_c'' &= \delta_\theta l_{-\theta} + \sum_\alpha \delta_\alpha n'_\alpha(c) l_\alpha \\ &= (\delta_\theta l_{-\theta} + \sum_\alpha \delta_\alpha n'_\alpha(a) l_\alpha) + \sum_\alpha \delta_\alpha (n'_\alpha(c) - n'_\alpha(a)) l_\alpha \\ &= \delta_a l_a'' + \delta_\theta l_b' \end{aligned}$$

Hence $l_c'' = l_a'' + l_b' \geq l_a + l_b'$ by induction hypothesis. By axiom (C1) and because $l_b' \geq l_b$, we get $l_c'' \geq l_a + l_b \geq l_{a+b} = l_c$.

Now we do an induction on height for all roots of Φ_{nd} . Basis: consider the lowest root $-h$. Because Φ_{nd} is non-simply laced, there exist two short roots $a, b \in \Phi_{\text{nd}}$ such that $-h = a + b$. In particular, $\delta_a = \delta_b = \delta_\theta$. Then:

$$\begin{aligned} -h &= -\delta_\theta \theta + \sum_{\alpha} \delta_{\alpha} n'_{\alpha}(h) \alpha \\ a &= -\theta + \sum_{\alpha} \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) \alpha \\ b &= -\theta + \sum_{\alpha} \frac{\delta_{\alpha}}{\delta_b} n'_{\alpha}(b) \alpha \\ (\delta_\theta - 2)\theta &= \sum_{\alpha} \left(\delta_{\alpha} n'_{\alpha}(h) - \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) - \frac{\delta_{\alpha}}{\delta_b} n'_{\alpha}(b) \right) \alpha \\ &= \sum_{\alpha} (\delta_\theta - 2) n_{\alpha}(\theta) \alpha \end{aligned}$$

Hence, we obtain:

$$\begin{aligned} l''_{-h} - l''_a - l''_b &= \left(\delta_\theta l_{-\theta} + \sum_{\alpha} n'_{\alpha}(-h) \delta_{\alpha} l_{\alpha} \right) - \left(l_{-\theta} + \sum_{\alpha} \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) l_{\alpha} \right) \\ &\quad - \left(l_{-\theta} + \sum_{\alpha} \frac{\delta_{\alpha}}{\delta_b} n'_{\alpha}(b) l_{\alpha} \right) \\ &= (\delta_\theta - 2) l_{-\theta} + \sum_{\alpha} \left(\delta_{\alpha} n'_{\alpha}(-h) - \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) - \frac{\delta_{\alpha}}{\delta_b} n'_{\alpha}(b) \right) l_{\alpha} \\ &= (\delta_\theta - 2)(l_{-\theta} + l'_{\theta}) \end{aligned}$$

Because $\delta_\theta = d' \geq 2$ and $l_{-\theta} + l'_{\theta} \geq l_{-\theta} + l_{\theta} \geq 0$, we have $l''_{-h} \geq l''_a + l''_b$. By the case of short roots, we know that $l''_a \geq l_a$ and $l''_b \geq l_b$. Hence, by axiom (C1), we have $l''_{-h} \geq l_a + l_b \geq l_{a+b} = l_{-h}$.

Induction step: we consider the length of a root $c \neq -h$. The case of short roots has been treated. Let $c \neq -h \in \Phi_{\text{nd}}$ be a long root and we assume that $l''_a \geq l_a$ for any root a lower than c in Φ_{nd} . We have $c = c^\delta = -\delta_\theta \theta + \sum_{\alpha} n'_{\alpha}(c) \delta_{\alpha} \alpha$. By Lemma 4.2.1, there exist $a \in \Phi_{\text{nd}}$ and $b \in \Phi_{\text{nd}}^+$ such that $c = a + b$.

If a is long, we have $a = a^\delta = -\delta_\theta \theta + \sum_{\alpha} n'_{\alpha}(a) \delta_{\alpha} \alpha$. Hence, $\delta_{\alpha} n'_{\alpha}(c) = \delta_{\alpha} n'_{\alpha}(a) + n_{\alpha}(b)$. As a consequence, $l''_c = l''_a + l'_b$. By induction hypothesis, $l''_a \geq l_a$ because c is strictly higher than a . Hence $l''_c \geq l_a + l'_b \geq l_a + l_b \geq l_{a+b} = l_c$ by axiom (C1).

Otherwise, a is a short root, so that $\delta_a = \delta_\theta = d'$. Hence $a = -\theta + \sum_{\alpha} \frac{\delta_{\alpha}}{\delta_\theta} n'_{\alpha}(a) \alpha$. We have: $0 = a + b - c = (\delta_\theta - 1)\theta + \sum_{\alpha} \left(\frac{\delta_{\alpha}}{\delta_\theta} n'_{\alpha}(a) + n_{\alpha}(b) - n'_{\alpha}(c) \delta_{\alpha} \right) \alpha$. By uniqueness of coefficients, for any $\alpha \in \Delta$, we have $(\delta_\theta - 1)n_{\alpha}(\theta) = \frac{\delta_{\alpha}}{\delta_\theta} n'_{\alpha}(a) + n_{\alpha}(b) - n'_{\alpha}(c) \delta_{\alpha}$. Hence $l''_c - l''_a - l'_b = (\delta_\theta - 1)l_{-\theta} + \sum_{\alpha} (\delta_\theta - 1)n_{\alpha}(\theta) l_{\alpha} = (\delta_\theta - 1)(l_{-\theta} + l'_{\theta})$. Because $l_{-\theta} + l'_{\theta} \geq l_{-\theta} + l_{\theta} \geq 0$ by axiom (C2), we obtain $l''_c \geq l''_a + l'_b$. By induction hypothesis, $l''_a \geq l_a$. Hence $l''_c \geq l_a + l_b \geq l_{a+b} = l_c$ by axiom (C1). This finishes the induction.

Finally if c is a multipliable root, then $l''_{2c} = 2l''_c \geq 2l_c \geq l_{2c}$ by axiom (C0). This finishes the proof of (2).

(3) We now establish inclusions $U_{c, l''_c} \subset [H, H]$ of valued root groups, in the order from the longest roots to the shortest roots. According to Φ is a reduced root system or not, there are one, two or three distinct length of roots.

Let $c \neq -\theta$ be a root. Write it as a sum of two non-collinear roots $c = a + b$. We want to apply Proposition 4.1.3, with suitable values $l''_a \in \Gamma_a$, $l'_b \in \Gamma_b$ and $\widehat{l}_c \in \Gamma_c$ such that $l''_c \geq \widehat{l}_c = l''_a + l'_b$, to prove that $U_{c, l''_c} \subset [H, H]$. Because in 4.1.3, there remains a term v'' , we have to be careful in the order of the steps of this proof. We proceed step by step from the longest length to the shortest length of the roots, and we treat the case, when it happens, of $c = -h \neq -\theta$ separately, at the end. We denote by $(a, b) = \{ra + sb, r, s \in \mathbb{N}\} \cap \Phi$ and by $\Phi(a, b) = (\mathbb{Z}a + \mathbb{Z}b) \cap \Phi$. Be careful that in general, $\Phi(a, b) \neq (\mathbb{R}a + \mathbb{R}b) \cap \Phi$.

• **Case of a divisible root:** Suppose that $c \neq -h$ is a divisible root. Hence Φ is non-reduced and $\delta_c = \delta_\theta = d' = 2$. Moreover $2\theta = h$. By Lemma 4.2.1 applied to Φ_{nm} , there exist non-collinear roots $a, b \in \Phi_{\text{nm}}$ such that $b \in \Phi_{\text{nm}}^+$ and $c = a + b$. Moreover, a, b have to be non-divisible and we have $\delta_a = \delta_b = 1$. As above, one can show again that $l''_c = 2l''_{\frac{c}{2}} = l''_a + l''_b$. By Proposition 4.1.3, for any $u \in U_{c, l''_c}$, there exist elements $v \in U_{a, l''_a}$ and $v' \in U_{b, l''_b}$ such that $u = [v, v']$. Hence $U_{c, l''_c} \subset [H, H]$.

• **Case of a non-divisible long root:** Let c be a long root of Φ_{nd} . Then $\delta_c = 1$ by definition. Suppose that $c = c^\delta \notin \{-\theta, -h\}$. By Lemma 4.2.1 applied to Φ_{nd} , there exist non-collinear roots $a, b \in \Phi$ such that $b \in \Phi_{\text{nd}}^+$ and $c = a + b$.

First subcase: $\Phi(a, b)$ is of type A_2 . We have $(a, b) = \{a, b, a + b\}$ and we have shown in (2) that $l''_c \geq l''_a + l''_b$. By Proposition 4.1.3, for any $u \in U_{c, l''_c}$, there exist elements $v \in U_{a, l''_a}$ and $v' \in U_{b, l''_b}$ such that $u = [v, v']$. Hence $U_{c, l''_c} \subset [H, H]$ because $l''_a \geq l_a$ and $l''_b \geq l_b$.

Second subcase: $\Phi(a, b)$ is of type B_2 or G_2 . We have $(a, b) = \{a, b, a + b\}$ and $\delta_a = \delta_b = \delta_\theta$ because in this case, necessarily, the long root c is the sum of two short roots. We have shown that $l''_c \geq l''_a + l''_b$. By Proposition 4.1.3, for any $u \in U_{c, l''_c}$, there exist elements $v \in U_{a, l''_c - l''_b}$ and $v' \in U_{b, l''_b}$ such that $u = [v, v']$. Hence $U_{c, l''_c} \subset [H, H]$.

Third subcase: $\Phi(a, b)$ is of type BC_2 . Then a and b are multipliable, and we have $\delta_a = \delta_b = 2$. If $a \neq -\theta$, we define $a' = a - b \in \Phi_{\text{nm}}$ and $b' = 2b \in \Phi_{\text{nm}}$. Then a' is a long non-divisible root and b' is a divisible root. We have $\delta_{a'} = \delta_c = 1$ and $2a' + b' = 2a$. Hence $a' = -\delta_\theta \theta + \sum_\alpha n'_\alpha(a')\delta_\alpha \alpha$ and $b' = 2b = \sum_\alpha 2n_\alpha(b)\alpha$. For any $\alpha \in \Delta$, we obtain $n'_\alpha(c)\delta_\alpha = n'_\alpha(a')\delta_\alpha + 2n_\alpha(b)$. Hence $l''_c = \delta_\theta l_{-\theta} + \sum_\alpha n'_\alpha(c)\delta_\alpha l_\alpha = l''_{a'} + 2l'_b = l''_{a'} + l'_{b'}$.

We have $-2\theta + \sum_\alpha n'_\alpha(a')\delta_\alpha \alpha = a' = a + b = \left(-\theta + \sum_\alpha \frac{\delta_\alpha}{2} n'_\alpha(a)\alpha\right) + \sum_\alpha n_\alpha(b)\alpha$. For any $\alpha \in \Delta$, we obtain $n'_\alpha(a')\delta_\alpha - n_\alpha(\theta) = \frac{\delta_\alpha}{2} n'_\alpha(a) + n_\alpha(b)$. Hence:

$$\begin{aligned} l''_{a'} + l'_{b'} &= \delta_\theta l_{-\theta} + \sum_\alpha \left(n'_\alpha(a')\delta_\alpha + n_\alpha(b)\right) l_\alpha \\ &= 2l_{-\theta} + \sum_\alpha \left(\frac{\delta_\alpha}{2} n'_\alpha(a) + n_\alpha(\theta)\right) l_\alpha \\ &= 2l_{-\theta} + \frac{1}{2}(2l''_a - 2l_{-\theta}) + l'_\theta \\ &= (l_{-\theta} + l'_\theta) + \frac{1}{2}l''_{2a} \end{aligned}$$

Because $l_{-\theta} + l'_\theta \geq 0$, we get $2l''_{a'} + l'_{b'} = 2(l''_{a'} + l'_{b'}) \geq l''_{2a}$. By Proposition 4.1.3, for any $u \in U_{c, l''_c}$, there exist elements $v \in U_{a', l''_{a'}}$ and $v' \in U_{b', l'_{b'}}$ and $v'' \in U_{2a'+b', 2l''_{a'}+l'_{b'}}$ such that $u = [v, v']v''$. We have already shown, because $2a' + b' = 2a \neq -2\theta$ is a divisible root, that the group $U_{2a'+b', 2l''_{a'}+l'_{b'}} \subset U_{2a, l''_{2a}}$ is a subgroup of $[H, H]$. Hence $U_{c, l''_c} \subset [H, H]$.

If $a = -\theta$, we define $a' = 2a \in \Phi_{\text{nm}}$ and $b' = b - a = b + \theta \in \Phi_{\text{nm}}^+$. In the same way, we obtain $l''_c = l''_{a'} + l'_{b'}$ and $l''_{a'} + 2l'_{b'} = 2l''_b = l''_{b'}$. By Proposition 4.1.3, for any $u \in U_{c, l''_c}$, there exist elements $v \in U_{a', l''_{a'}}$ and $v' \in U_{b', l'_{b'}}$ and $v'' \in U_{a'+2b', l''_{a'}+2l'_{b'}}$ such that $u = [v, v']v''$. We have already shown, in the case of a divisible root, that the group $U_{a'+2b', l''_{a'}+2l'_{b'}} = U_{2b, l''_{2b}}$ is a subgroup of $[H, H]$. Hence $U_{c, l''_c} \subset [H, H]$.

• **Case of a short root:** Let $c \in \Phi_{\text{nd}}$ be a short root of $c \in \Phi_{\text{nd}}$. Then $\delta_c = \delta_\theta$ by definition. Suppose that $c \neq -\theta$ and that $-c^D$ is not the highest root of Φ_{nd}^D . By Lemma 4.2.7 applied to Φ_{nd} , there exist non-collinear roots $a, b \in \Phi$ such that $b \in \Phi_{\text{nd}}^+$, the root a is short and $c = a + b$.

First subcase: case of two short roots a and b . We have $\delta_a = \delta_b = \delta_c = \delta_\theta$ and we have shown in (2) that $l''_c = l''_a + l''_b$. The rank 2 root subsystem

$\Phi(a, b)$ is of type A_2 or G_2 . Moreover, when $\Phi(a, b)$ is of type G_2 , we have $(a, b) = \{a, b, a + b, 2a + b, a + 2b\}$. By Proposition 4.1.3, for any $u \in U_{c, l'_c}$, there exist elements $v \in U_{a, l'_a}$ and $v' \in U_{b, l'_b}$ and $v'' \in U_{2a+b, 2l'_a+l'_b} U_{a+2b, l'_a+2l'_b}$ if $\Phi(a, b)$ is of type G_2 , $v'' = 1$ if $\Phi(a, b)$ is of type A_2 , such that $u = [v, v']v''$.

It remains to prove that $v'' \in [H, H]$. In the G_2 case, we have $\delta_{2a+b} = \delta_{a+2b} = 1$. Moreover, $2a + b = 2\left(-\theta + \sum_{\alpha} \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) \alpha\right) + \sum_{\alpha} n_{\alpha}(b) \alpha = -\delta_{\theta} \theta + \sum_{\alpha} \left(2 \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) + n_{\alpha}(b) + (\delta_{\theta} - 2) n_{\alpha}(\theta)\right) \alpha$. We have:

$$\begin{aligned} l''_{2a+b} &= \delta_{\theta} l_{-\theta} + \sum_{\alpha} \left(2 \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) + n_{\alpha}(b) + (\delta_{\theta} - 2) n_{\alpha}(\theta)\right) l_{\alpha} \\ &= \delta_{\theta} l_{-\theta} + \frac{2}{\delta_a} (\delta_a l''_a - \delta_{\theta} l_{-\theta}) + l'_b + (\delta_{\theta} - 2) l'_{\theta} \\ &= 2l''_a + l'_b + (\delta_{\theta} - 2)(l_{-\theta} + l'_{\theta}) \end{aligned}$$

In the same way, one can show that $l''_{a+2b} = l''_a + 2l'_b + (\delta_{\theta} - 1)(l'_{\theta} + l_{-\theta})$.

If $\delta_{\theta} = 1$, because $l_{-\theta} + l'_{\theta} \geq 0$, we get $l''_{2a+b} \leq 2l''_a + l'_b$ and $l''_{a+2b} = l''_a + 2l'_b$. Hence, we get $U_{2a+b, l''_{2a+b}} \supset U_{2a+b, 2l''_a+l'_b}$ and $U_{a+2b, l''_{a+2b}} = U_{a+2b, l''_a+2l'_b}$.

Otherwise, $\delta_{\theta} = 3$ and G is a triality D_4 . In that case, we assumed that $l_{-\theta} + l'_{\theta} \leq \omega(\varpi_{L'}) = 0^+ \in \Gamma_{L'}$. Because $l''_{a+2b}, l''_{2a+b} \in \Gamma_{L_d} = 3\Gamma_{L'}$, we obtain that $0 \leq (\delta_{\theta} - 1)(l'_{\theta} + l_{-\theta}) < 3\omega(\varpi_{L'}) = 0^+ \in \Gamma_{L_d}$. The same is for $(\delta_{\theta} - 1)(l'_{\theta} + l_{-\theta})$. Hence, we have the equalities of root groups: $U_{a+2b, l''_a+2l'_b} = U_{a+2b, l''_{a+2b}+(\delta_{\theta}-1)(l'_{\theta}+l_{-\theta})} = U_{a+2b, l''_{a+2b}}$ and $U_{2a+b, 2l''_a+l'_b} = U_{2a+b, l''_{2a+b}+(\delta_{\theta}-2)(l'_b+l_{-\theta})} = U_{2a+b, l''_{2a+b}}$.

In both cases, because $2a + b$ and $a + 2b$ are long and different from $-h$, we have shown that the root groups $U_{2a+b, l''_{2a+b}}$ and $U_{a+2b, l''_{a+2b}}$ are contained in $[H, H]$. Thus, $v'' \in [H, H]$. Hence $U_{c, l'_c} \subset [H, H]$.

Second subcase: a is short and b is long. We have $\delta_a = \delta_c = \delta_{\theta}$ and $\delta_b = 1$. The rank 2 root subsystem $\Phi(a, b)$ is of type B_2 or BC_2 . Precisely, we have $(a, b) = \{a, b, a + b, 2a + b\}$ if Φ is a reduced root system and $(a, b) = \{a, b, a + b, 2a, 2a + b, 2a + 2b\}$ otherwise. We have $\delta_a = \delta_c = \delta_{\theta}$ and $\delta_b = \delta_{2a+b} = 1$. We have $\delta_c c = \delta_{\theta} \left(-\theta + \sum_{\alpha} \left(\frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) + n_{\alpha}(b)\right) \alpha\right) = -\delta_{\theta} \theta + \sum_{\alpha} (\delta_{\alpha} n'_{\alpha}(a) + \delta_{\theta} n_{\alpha}(b)) \alpha$. Hence $\delta_c l'_c = \delta_a l''_a + \delta_{\theta} l'_b$. Thus $l'_c = l''_a + l'_b$. By Proposition 4.1.3, for any $u \in U_{c, l'_c}$, there exist elements $v \in U_{a, l'_a}$ and $v' \in U_{b, l'_b}$ and $v'' \in U_{2a+b, 2l''_a+l'_b}$ such that $u = [v, v']v''$.

It remains to check that $v'' \in [H, H]$. We have:

$$\begin{aligned} \delta_{2a+b}(2a + b) &= 2a + b = 2\left(-\theta + \sum_{\alpha} \frac{\delta_{\alpha}}{\delta_a} n'_{\alpha}(a) \alpha\right) + \sum_{\alpha} n_{\alpha}(b) \alpha \\ &= -\delta_{\theta} \theta + \sum_{\alpha} \left(\delta_{\alpha} \frac{2}{\delta_a} n'_{\alpha}(a) + n_{\alpha}(b) + (\delta_{\theta} - 2) n_{\alpha}(\theta)\right) \alpha \end{aligned}$$

Hence:

$$\begin{aligned} l''_{2a+b} &= \delta_{\theta} l_{-\theta} + \frac{2}{\delta_a} (\delta_a l''_a - \delta_{\theta} l_{-\theta}) + l'_b + (\delta_{\theta} - 2) l'_{\theta} \\ &= \delta_{\theta} l_{-\theta} + 2l''_a - 2l_{-\theta} + l'_b + (\delta_{\theta} - 2) l'_{\theta} \\ &= 2l''_a + l'_b + (\delta_{\theta} - 2)(l_{-\theta} + l'_{\theta}) \end{aligned}$$

Because $\delta_{\theta} \in \{1, 2\}$ and $l_{-\theta} + l'_{\theta} \geq 0$, we obtain the inequality $l''_{2a+b} \leq 2l''_a + l'_b$. Since $2a + b$ is a long root of Φ_{nd} , we have already shown that $U_{2a+b, 2l''_a+l'_b} \subset U_{2a+b, l''_{2a+b}} \subset [H, H]$. Hence $v'' \in [H, H]$ and it follows that $U_{c, l'_c} \subset [H, H]$.

Now, two cases of roots may remain: the negative root c such that $-c^D$ is the highest root of Φ^D when $h = \theta$; and the negative root $c = -h$ when $h \neq \theta$.

• **The lowest dual root:** Assume that c is the negative root of Φ_{nd} such that $-c^D$ is the highest root of Φ_{nd}^D and $h = \theta \neq -c$ (this case appears only if L'/L_d is unramified and Φ is not a simply laced root system). In this case, we have $\delta_a = \delta_b = \delta_c = \delta_{\theta} = 1$ and the rank 2 root subsystem $\Phi(a, b)$ is reduced.

By Lemma 4.2.1(2), there exists $a \in \Phi_{\text{nd}}^-$ and $b \in \Phi_{\text{nd}}^+$ such that $c = a + b$. If a is short, we can proceed as before. Hence we assume that a is a long root, b and c are short roots.

If $\Phi(a, b)$ is of type B_2 , then $(a, b) = \{a, b, a + b, a + 2b\}$ and we have the equalities $l''_{a+b} = l''_a + l'_b$ and $l''_{a+2b} = l''_a + 2l'_b$. By Proposition 4.1.3, for any $u \in U_{c, l''_c}$, there exist elements $v \in U_{a, l''_a}$ and $v' \in U_{b, l'_b}$ and $v'' \in U_{a+2b, l''_a+2l'_b}$ such that $u = [v, v']v''$. Since $a + 2b$ is a long root of $\Phi_{\text{nd}} = \Phi$, we have already shown that $U_{a+2b, l''_a+2l'_b} = U_{a+2b, l''_{a+2b}} \subset [H, H]$. Hence $U_{c, l''_c} \subset [H, H]$.

If $\Phi(a, b)$ is of type G_2 , then $(a, b) = \{a, b, a + b, a + 2b, a + 3b, 2a + 3b\}$. We have the equalities $l''_{a+b} = l''_a + l'_b$, $l''_{a+2b} = l''_a + 2l'_b$ and $l''_{a+3b} = l''_a + 3l'_b$. Moreover, we have $l''_{2a+3b} = 2l''_a + 3l'_b - (l_{-\theta} + l'_\theta) \leq 2l''_a + 3l'_b$. By Proposition 4.1.3, for any $u \in U_{c, l''_c}$, there exist elements $v \in U_{a, l''_a}$ and $v' \in U_{b, l'_b}$ and $v'' \in U_{a+2b, l''_a+2l'_b} U_{a+3b, l''_a+3l'_b} U_{2a+3b, 2l''_a+3l'_b}$ such that $u = [v, v']v''$. Since $a + 3b$ and $2a + 3b$ are long roots of $\Phi_{\text{nd}} = \Phi$, we have already shown that $U_{a+3b, l''_a+3l'_b} = U_{a+3b, l''_{a+3b}} \subset [H, H]$ and that $U_{2a+3b, 2l''_a+3l'_b} \subset U_{2a+3b, l''_{2a+3b}} \subset [H, H]$. Since $a + 2b \neq -\theta$ can be written as the sum of the two short roots b and $a + b$, we have shown that $U_{a+2b, l''_a+2l'_b} = U_{a+2b, l''_{a+2b}} \subset [H, H]$. Hence $U_{c, l''_c} \subset [H, H]$.

• **The lowest root:** To conclude, it remains to treat the case, when it appears, of the root $-h \neq -\theta$ where h is the highest root of Φ (this appears only for G of type ${}^2A_{2l+1}$, ${}^2D_{l+1}$, 2E_6 , 3D_4 or 6D_4 with a ramified extension L'/L_d). In this case, we have $\delta_\theta > 1$ and h is a long root. In particular, the integer $(\delta_\theta - 2)$ is non-negative. We write h as a sum $h = c = a + b$ of two short roots a and b , so that $\delta_a = \delta_b = \delta_\theta$ and $\delta_c = 1$. Moreover $(a, b) = \{a, b, a + b\}$. We have:

$$\begin{aligned} c = a + b &= \left(-\theta + \sum_{\alpha} \frac{\delta_\alpha}{\delta_a} n'_\alpha(a) \alpha \right) + \left(-\theta + \sum_{\alpha} \frac{\delta_\alpha}{\delta_b} n'_\alpha(b) \alpha \right) \\ &= -2\theta + \sum_{\alpha} \left(\frac{\delta_\alpha}{\delta_\theta} n'_\alpha(a) + \frac{\delta_\alpha}{\delta_\theta} n'_\alpha(b) \right) \alpha \\ &= -\delta_\theta \theta + \sum_{\alpha} \left(\frac{\delta_\alpha}{\delta_\theta} n'_\alpha(a) + \frac{\delta_\alpha}{\delta_\theta} n'_\alpha(b) + (\delta_\theta - 2) n_\alpha(\theta) \right) \alpha \end{aligned}$$

Hence we obtain:

$$\begin{aligned} l''_c &= \delta_\theta l_{-\theta} + \frac{1}{\delta_\theta} (\delta_a l''_a - \delta_\theta l_{-\theta}) + \frac{1}{\delta_\theta} (\delta_b l''_b - \delta_\theta l_{-\theta}) + (\delta_\theta - 2) l'_\theta \\ &= l''_a + l''_b + (\delta_\theta - 2) (l_{-\theta} + l'_\theta) \\ &\geq l''_a + l''_b \end{aligned}$$

By Proposition 4.1.3, for any $u \in U_{c, l''_c} \subset U_{c, l''_a+l''_b}$, there exist elements $v \in U_{a, l''_a}$ and $v' \in U_{b, l''_b}$ such that $u = [v, v']$. This finishes the proof. \square

4.2.10 Remark. Proposition 4.2.6 and Proposition 4.2.9 do not restrict the choice of the basis Δ but only the choice of values l_a . In fact, the conditions $l_a \in \Gamma_a$ for any $a \in \Delta$ and $l_{-\theta} \in \Gamma_{-\theta}$ limit the available choices for the basis Δ .

4.2.11 Lemma. *Let Φ be a non-reduced root system and Δ be a basis of Φ . Let $a \in \Delta$ be the multipliable simple root. Let θ be the half highest root of Φ relatively to the basis Δ . Then $\Delta' = (\Delta \cup \{-\theta\}) \setminus \{a\}$ is another basis of Φ ; and $-a$ is the half highest root of Φ relatively to the basis Δ' .*

Proof. We consider the following Euclidean geometric realisation of the root system $\Phi = \{\pm e_i, 1 \leq i \leq l\} \cup \{\pm e_i \pm e_j, 1 \leq i < j \leq l\} \cup \{\pm 2e_i, 1 \leq i \leq l\}$ where (e_i) denotes the canonical basis of the Euclidean space \mathbb{R}^l . We denote by $a_i = e_i - e_{i+1}$ for any $1 \leq i \leq l-1$ and by $a_l = e_l$. The set $\Delta = \{a_1, \dots, a_l\}$ is a basis of Φ and $\theta = e_1 = a_1 + \dots + a_l$ is the half highest root of Φ .

Let $w \in \mathrm{GL}_l(\mathbb{R})$ be the element of the Weyl group $W(\Phi)$ defined by $w(e_i) = -e_{l-i+1}$. We observe that w stabilises $\Delta \setminus \{a_l\}$, that $w(-\theta) = a_l$ and that $w(a_l) = -\theta$.

If D is a half-space of \mathbb{R}^l defining the basis Δ , then $w(D)$ is also a half-space of \mathbb{R}^l and it defines the basis $\Delta' = (\Delta \setminus \{a_l\}) \cup \{-\theta\}$. The half highest root of Φ relatively to Δ' is then $-a_l$. \square

4.2.3 Lower bounds for valued root groups of the Frattini subgroup

We want to apply Propositions 4.2.6 and 4.2.9 to the maximal pro- p subgroup P corresponding to the fundamental alcove \mathbf{c}_{af} described in Section 3.1.

4.2.12 Theorem. *Assume that the irreducible relative root system Φ is of rank $l \geq 2$ and that the residue characteristic p of K satisfies Hypothesis 4.1.2. Let P be a maximal pro- p subgroup of $G(K)$ and let \mathbf{c} be the (unique) alcove fixed by P . For any root $a \in \Phi$, if the wall $\mathcal{H}_{a, f'_c(a)}$ (this notation has been defined in Section 3.1.1) contains a panel of \mathbf{c} , then we have $[P, P] \supset U_{a, f'_c(a)^+}$; otherwise, we have $[P, P] \supset U_{a, f'_c(a)}$.*

Proof. We normalize $\Gamma_{L'} = \mathbb{Z}$. Up to conjugation, we can assume that $\mathbf{c} = \mathbf{c}_{\mathrm{af}}$ is the fundamental alcove, defined in Section 3.1.2, and bounded by the following walls:

- $\mathcal{H}_{a,0}$ for all simple roots $a \in \Delta$;
- $\mathcal{H}_{-\theta,1}$ if Φ is reduced;
- $\mathcal{H}_{-\theta, \frac{1}{2}}$ if Φ is non-reduced.

For any root $a \in \Phi$, we have the following value:

- $f'_c(a) = 0$ if $a \in \Phi^+$;
- $f'_c(a) = \frac{\delta_a}{\delta_a} \in \{1, d'\}$ if $a \in \Phi^-$ and Φ is reduced;
- $f'_c(a) = \frac{1}{\delta_a} \in \{\frac{1}{2}, 1\}$ if $a \in \Phi_{\mathrm{nd}}^-$ and Φ is non-reduced.

The wall bounding the alcove \mathbf{c} are directed by the relative roots $\Delta \cup \{-\theta\}$. Hence, for any $a \in \Delta \cup \{-\theta\}$, we get $f_c(a) = f'_c(a) \in \Gamma_a$. Moreover, $f_c(-\theta) = 1$ and $l'_\theta = 0$ so that the sum satisfies $f_c(-\theta) + l'_\theta = 1 = \omega(\varpi_{L'})$. As a consequence, we can apply Propositions 4.2.6 and 4.2.9 to the group P and the values $l_c = f_c(c)$ where $c \in \Phi$.

For any non-divisible non-simple positive root $b \in \Phi_{\mathrm{nd}}^+ \setminus \Delta$, by Proposition 4.2.6, we get $l'_b = 0$. Hence $[P, P] \supset U_{b,0} = U_{b,l_b}$.

For any root $c \in \Phi^- \setminus \{-\theta, -2\theta\}$, by Proposition 4.2.9, we get $\delta_c l_c'' = \delta_\theta f'_c(-\theta)$. If Φ is reduced, then we have $l_c'' = \frac{\delta_\theta}{\delta_c} = f'_c(c)$. If Φ is non-reduced, then we have $l_c'' = \frac{1}{\delta_c} = f'_c(c)$ because $\delta_{-\theta} l_{-\theta} = 1$. Hence $[P, P] \supset U_{c,l_c}$.

We suppose that Φ is reduced. Let $a \in \Delta \cup \{-\theta\}$. Then, by Proposition 2.2.3, we know that $[P, P] \supset U_{a, l_a^+}$.

We suppose that Φ is non-reduced. Let $a \in \Delta$. By Proposition 4.2.9, we get $\delta_a l_a'' = \delta_\theta f'_c(-\theta)$. We have $l_a'' = \frac{1}{\delta_a} = 0^+ = f'_c(a)^+$. Indeed, if a is multipliable, $l_a'' = \frac{1}{2}$; otherwise $l_a'' = 1$ is the smallest positive value of Γ_a . Hence $[P, P] \supset U_{a, l_a^+}$.

Finally, when Φ is non-reduced, we can apply Lemma 4.2.11 to exchange the roles of the multipliable simple root $a \in \Delta$ and the opposite of the half

highest root $-\theta$. We write $\theta = \sum_{b \in \Delta} n_b b$ where $n_b \in \mathbb{N}^*$, so that $-\theta = \theta + (-2\theta) = n_a a + \sum_{b \in \Delta \setminus \{a\}} n_b b + 2(-\theta)$. Thus, by applying Proposition 4.2.9 to the basis $\Delta' = (\Delta \setminus \{a\}) \cup \{-\theta\}$, we get $l''_{-\theta} = 2l_{-\theta} = 1 = l_{\theta}^+$. \square

4.2.13 Remark. As an immediate consequence, the derived group $[P, P]$ contains $U_{c, f'_{B(\mathbf{c}, 1) \cap \Lambda}(c)}$ for any root $c \in \Phi$.

In the rank 1 case, we have a lack of rigidity that could make $[P, P]$ smaller than expected. Typically, Propositions 4.2.6 and 4.2.9 cannot be applied.

4.2.14 Corollary. *We assume that $p \neq 2$ and that the structure constant $c_{1,1;\alpha,\beta}$ are in \mathcal{O}_K^\times for all pairs of non-collinear roots α, β . For any non-divisible root $a \in \Phi_{\text{nd}}$ and any maximal pro- p subgroup P of $G(K)$, we write $P \cap U_a(K) = U_{a, l_a}$ where $l_a \in \Gamma_a$. If $a \in \Delta \cup \{-\theta\}$,*

- *if a is a non-multipliable root or if the extension L_a/L_{2a} is ramified, then we have the equality $[P, P] \cap U_a(K) = U_{a, l_a^+}$.*
- *if a is multipliable and if the extension L_a/L_{2a} is unramified, then we have the inclusions $U_{a, l_a^+} \subset [P, P] \cap U_a(K) \subset U_{a, l_a^+} U_{2a, 2l_a}$.*

If $a \in \Phi \setminus (\Delta \cup \{-\theta\})$, then we have the equality $[P, P] \cap U_a(K) = U_{a, l_a}$.

Proof. This results immediately from Theorem 4.2.12 and Proposition 3.2.2. \square

5 Generating set of a maximal pro- p subgroup

As before, G is an almost- K -simple quasi-split simply-connected K -group and P is a maximal pro- p subgroup of $G(K)$. In Corollary 5.2.2, we obtain the minimal number of topological generators of the pro- p Sylow P in the various cases.

In order to give explicit formulas for these numbers, we introduce the following integers. We denote by e' the ramification index of L'/L_d and by f' its residue degree; we let $m = \log_p(\text{Card}(\kappa_K))$ so that $\kappa_K \simeq \mathbb{F}_{p^m}$. Moreover, when G is assumed to be almost- K -simple instead of absolutely simple, we denote by e the ramification index of L_d/K and by f its residue degree.

5.1 The Frattini subgroup

In order to compute a minimal generating set of the maximal pro- p subgroup P , we know by [DdSMS99, 1.9] that it suffices to compute a minimal generating set of the p -elementary commutative group $P/\text{Frat}(P)$, where $\text{Frat}(P)$ denotes the Frattini subgroup of P . According to [Loi16, 3.2.9], we know that $P = \left(\prod_{a \in \Phi_{\text{nd}}^-} U_{a, \mathbf{c}} \right) T(K)_b^+ \left(\prod_{a \in \Phi_{\text{nd}}^+} U_{a, \mathbf{c}} \right)$ as directly generated product, where \mathbf{c} is a suitable alcove of $X(G, K)$. Up to conjugation, we can — and do — assume that $\mathbf{c} = \mathbf{c}_{\text{af}}$.

We want to describe the Frattini subgroup $\text{Frat}(P)$, in the same way, in terms of valued root groups U_{a, \widehat{l}_a} , with suitable values $\widehat{l}_a \in \mathbb{R}$, and a subgroup of $T(K)_b^+$ that we have to determinate. Since P is a pro- p group, by [DdSMS99, 1.13], we have $\text{Frat}(P) = \overline{P^p[P, P]}$. Hence $P/\text{Frat}(P)$ is a $\mathbb{Z}/p\mathbb{Z}$ vector space of dimension $d(P)$ that we want to compute explicitly.

5.1.1 Theorem (Descriptions of the Frattini subgroup of a maximal pro- p subgroup: the reduced case). *We suppose that the relative root system Φ is reduced and that $p \neq 2$. If Φ is of type G_2 , we require that $p \geq 5$. Then:*

Profinite description: The pro- p group P is topologically of finite type and, in particular, $\text{Frat}(P) = P^p[P, P]$. Moreover, when K is of characteristic $p > 0$, we have $P^p \subset [P, P]$.

Description by the valued root groups datum: For any $a \in \Phi$, we set:

$$V_{a, \mathbf{c}} = \begin{cases} U_{a, f_{\mathbf{c}}(a)^+} & \text{if } a \in \Delta \cup \{-\theta\} \\ U_{a, \mathbf{c}} & \text{otherwise} \end{cases}$$

This group depends only on the root $a \in \Phi$ and the alcove $\mathbf{c} \subset \mathbb{A}$, not on the chosen basis Δ .

We have the following writing, as directly generated product:

$$\text{Frat}(P) = \left(\prod_{-a \in \Phi^+} V_{-a, \mathbf{c}} \right) T(K)_b^+ \left(\prod_{a \in \Phi^+} V_{a, \mathbf{c}} \right)$$

Geometrical description: The Frattini subgroup $\text{Frat}(P)$ is the maximal pro- p subgroup of the pointwise stabilizer in $G(K)$ of the combinatorial ball centered at \mathbf{c} of radius 1.

Proof. For any $a \in \Phi$, we let $l_a = f_{\mathbf{c}}(a)$, so that $l_a \in \Gamma_a$ for any $a \in \Delta \cup \{-\theta\}$ and the map $a \mapsto l_a$ is concave. We define $\hat{l}_a = \begin{cases} l_a^+ & \text{if } a \in \Delta \cup \{-\theta\} \\ l_a & \text{otherwise} \end{cases}$.

We define $Q = \prod_{a \in \Phi^-} U_{a, \hat{l}_a} \cdot T(K)_b^+ \cdot \prod_{a \in \Phi^+} U_{a, \hat{l}_a}$. We prove the chain of inclusions $Q \subset P^p[P, P] \subset \text{Frat}(P) \subset Q$.

The inclusion $P^p[P, P] \subset \overline{P^p[P, P]} = \text{Frat}(P)$ is immediate.

By Corollary 3.2.7, we have $\text{Frat}(P) \subset Q$.

If the reduced irreducible root system Φ is of rank $l \geq 2$, by Theorem 4.2.12, we have $\forall a \in \Phi$, $[P, P] \supset U_{a, \hat{l}_a}$. If Φ is of rank 1, by Proposition 2.2.3, we have $\forall a \in \Phi$, $P^p[P, P] \supset U_{a, \hat{l}_a}$. Moreover, by Proposition 2.2.3, we also have $T^a(K)_b^+ \subset P^p[P, P]$ for any $a \in \Phi$. Because G is a simply-connected semisimple group, $T(K)_b^+$ is generated by the groups $T^a(K)_b^+$, hence $T(K)_b^+ \subset P^p[P, P]$. As a consequence, $Q \subset P^p[P, P]$.

Hence, we obtain (2): $Q = \text{Frat}(P) = P^p[P, P]$.

Moreover, if K is of positive characteristic, by Proposition 2.2.3 one can replace $[P, P]P^p$ by $[P, P]$ so that we get (1): $Q = [P, P]$.

(3) By Proposition 3.2.8, we know that $\text{Frat}(P) = Q$ is the maximal pro- p subgroup of the pointwise stabilizer of the combinatorial closure of the combinatorial unit ball centered in \mathbf{c} . \square

In the case of a non-reduced root system Φ , we have seen that computation of $[P, P]$ is different from the reduced case because of non-commutativity of root groups. We have to study this case separately.

5.1.2 Theorem (Descriptions of the Frattini subgroup of a maximal pro- p subgroup: the non-reduced case). *We suppose that Φ is a non-reduced root system of rank $l \geq 2$, and that $p \geq 5$. Then:*

Profinite description: The pro- p group P is topologically of finite type and, in particular, $\text{Frat}(P) = P^p[P, P]$.

Description by the valued root groups datum: Let $a \in \Phi_{\text{nd}}$ be a non-divisible root. If $a \notin \Delta \cup \{-\theta\}$, we set $V_{a, \mathbf{c}} = U_{a, \mathbf{c}}$.

If $a \in \Delta \cup \{-\theta\}$, we set:

$$V_{a,\mathbf{c}} = \begin{cases} U_{a,f_{\mathbf{c}}(a)^+} & \text{if } a \text{ is non-multipliable} \\ U_{a,f'_{\mathbf{c}}(a)^+} & \text{if } a \text{ is multipliable and } L'/L_d \text{ is ramified} \\ U_{a,f'_{\mathbf{c}}(a)^+} & \text{if } a \text{ is multipliable, } L'/L_2 \text{ is unramified and } f'_{\mathbf{c}}(a) \notin \Gamma'_a \\ U_{a,f'_{\mathbf{c}}(a)^+} U_{2a,2f'_{\mathbf{c}}(a)} & \text{if } a \text{ is multipliable, } L'/L_2 \text{ is unramified and } f'_{\mathbf{c}}(a) \in \Gamma'_a \end{cases}$$

$$\text{Then } \text{Frat}(P) = \left(\prod_{a \in \Phi_{\text{nd}}^-} V_{a,\mathbf{c}} \right) T(K)_b^+ \left(\prod_{a \in \Phi_{\text{nd}}^+} V_{a,\mathbf{c}} \right).$$

Proof. Let $Q = \left(\prod_{a \in \Phi_{\text{nd}}^-} V_{a,\mathbf{c}} \right) T(K)_b^+ \left(\prod_{a \in \Phi_{\text{nd}}^+} V_{a,\mathbf{c}} \right)$. By Corollary 3.2.7, we have $\text{Frat}(P) \subset Q$.

If Φ is of rank $l \geq 2$, by Theorem 4.2.12 and Lemma 2.3.12, we have $\forall a \in \Phi$, $[P, P] \supset V = \prod_{a \in \Phi_{\text{nd}}} V_{a,\mathbf{c}}$. For the multipliable simple root a , by Proposition 2.3.1 and Proposition 2.3.11, because $f_{\mathbf{c}_{\text{af}}}(a) = 0$, we have $\varepsilon = 0$, and so $T^a(K)_b^+ \subset [P, P]$. For any non-multipliable root $a \in \Phi$, by Propositions 2.2.3 and 2.3.11, we have $T^a(K)_b^+ \subset [P, P]$. Hence, $T(K)_b^+$ is a subgroup of $\text{Frat}(P)$. As a consequence, we have $Q \subset \text{Frat}(P)$.

Moreover, because Q is an open subgroup of P (of finite index), the Frattini subgroup $\text{Frat}(P) = Q$ is open in P . By [DdSMS99, 1.14], we know that P is topologically of finite type. By [DdSMS99, 1.20], we deduce $\text{Frat}(P) = P^p[P, P]$. \square

5.2 Minimal number of generators

5.2.1 Corollary (of Theorems 5.1.1 and 5.1.2). *We assume $p \neq 2$.*

If the root system Φ is reduced, we assume that, at least, $p \neq 3$ or Φ is not of type G_2 . If the root system Φ is non-reduced, we assume that $p \geq 5$ and that Φ is not of rank 1.

Then $P/\text{Frat}(P)$ is isomorphic to the following direct product of p -elementary commutative groups: $\prod_{a \in \Phi} U_{a,\mathbf{c}}/V_{a,\mathbf{c}}$, where the groups $V_{a,\mathbf{c}}$ for $a \in \Phi$ are defined in Theorems 5.1.1 and 5.1.2.

Proof. Let $A = \prod_{a \in \Phi} U_{a,\mathbf{c}}/V_{a,\mathbf{c}}$ be the considered direct product of quotient groups. Let $B = \left(\prod_{a \in \Phi^-} U_{a,\mathbf{c}} \right) \times T(K)_b^+ \times \left(\prod_{a \in \Phi^+} U_{a,\mathbf{c}} \right)$ be the direct product of the valued root groups with respect to $\mathbf{c} = \mathbf{c}_{\text{af}}$, and of the maximal pro- p subgroup of the bounded torus. Let $C = \left(\prod_{a \in \Phi^-} V_{a,\mathbf{c}} \right) \times \{1\} \times \left(\prod_{a \in \Phi^+} U_{a,\mathbf{c}} \right)$ be the direct product of the valued root groups provided by Theorems 5.1.1 and 5.1.2.

We want to define a surjective group homomorphism $B \rightarrow P/\text{Frat}(P)$. Let $\pi : P \rightarrow P/\text{Frat}(P)$ be the quotient homomorphism. For any inclusion $j_a : U_{a,\mathbf{c}} \rightarrow P$ (resp. $j_0 : T(K)_b^+ \rightarrow P$), we define a group homomorphism $\phi_a = \pi \circ j_a : U_{a,\mathbf{c}} \rightarrow P/\text{Frat}(P)$ (resp. $\phi_0 = \pi \circ j_0$). Since $P/\text{Frat}(P)$ is commutative, the multiplication map induces a group homomorphism $\mu : B \rightarrow P/\text{Frat}(P)$. Applying [Loi16, 3.2.9] to P , we deduce that the homomorphism μ is surjective.

By Theorems 5.1.1(2) and 5.1.2(2), we get $\ker \mu = C$. Passing to the quotient, we deduce a group isomorphism $B/C \simeq P/\text{Frat}(P)$. Furthermore, there is a canonical group isomorphism $A \simeq B/C$. Hence $P/\text{Frat}(P)$ is isomorphic to A . \square

Since $P/\text{Frat}(P)$ is a p -elementary commutative group, we deduce that so are the quotient groups $U_{a,c}/V_{a,c}$. Hence, we can compute their dimension as \mathbb{F}_p -vector space. According to [DdSMS99, 1.9], we know that the minimal number of elements in a generating set of a pro- p group is $d(P) = \dim_{\mathbb{F}_p}(P/\text{Frat}(P))$. It can also be computed by $d(P) = \dim_{\mathbb{Z}/p\mathbb{Z}}(H^1(P, \mathbb{Z}/p\mathbb{Z}))$ according to [Ser94, 4.2 Corollaire 5]. We apply this to our maximal pro- p subgroup P of $G(K)$.

5.2.2 Corollary. *As above we assume that K is a non-Archimedean local field of residue characteristic p . We assume that G is an almost- K -simple simply-connected quasi-split K -group and that $p \neq 2$. We keep notations of 2.1.4. Let n be the rank of an irreducible subsystem of the absolute root system $\tilde{\Phi}(G_{\tilde{K}}, \tilde{K})$ and l be the rank of the irreducible relative root system $\Phi(G, K)$. Let f be the residue degree of L_d/K and $m = \log_p(\text{Card}(\kappa_K))$.*

(1) *If Φ is of type G_2 or if Φ is non-reduced, suppose that $p \geq 5$. If L'/L_d is ramified, then $d(P) = mf(l+1)$; if L'/L_d is unramified, then $d(P) = mf(n+1)$.*

(2) *Suppose that Φ is of type BC_1 and that $p \geq 5$. If L'/L_d is ramified, then $2mf \leq d(P) \leq 6mf$; if L'/L_d is unramified, then $3mf \leq d(P) \leq 9mf$.*

5.2.3 Remark (Summary in terms of quasi-split groups classification). We recall that f' denotes the residue degree of L'/L_d and that there are, case by case, identities between d , l and n . In Corollary 5.2.2, if the quasi-split group is of type ${}^dX_{n,l}$ (with notations of [Tit66]; Tits indices are not necessary in this study because of quasi-splitness assumption), we have $d(P) = mf\xi$ where:

Type	(in)equality	Assumption
${}^1X_l, l \geq 1, X \neq G$	$\xi = l + 1$	$p \geq 3$
1G_2	$\xi = 3$	$p \geq 5$
${}^2A_{2l-1}, l \geq 2$	$\xi = f'(l-1) + 2$	$p \geq 3$
${}^2D_{l+1}, l \geq 3$	$\xi = l + f'$	$p \geq 3$
2E_6	$\xi = 3 + 2f'$	$p \geq 3$
3D_4 and 6D_4	$\xi = 2 + f'$	$p \geq 5$
${}^2A_{2l}, l \geq 2$	$\xi = f'l + 1$	$p \geq 5$
2A_2	$f' + 1 \leq \xi \leq 3f' + 3$	$p \geq 5$

Proof. According to [Tit66, 3.1.2], there exists an absolutely simple group G' such that $G = R_{L_d/K}(G')$, so that $G(K) = G'(L_d)$. Because $\text{Card}(\kappa_{L_d}) = f\text{Card}(\kappa_K)$, we can assume that G is absolutely simple, so that $\tilde{\Phi}$ is irreducible and $m = \log_p(\text{Card}(\kappa_{L_d}))$.

(1) **Suppose that Φ is reduced.** By definition of the groups $V_{a,c}$ 5.1.1(2), we have $U_{a,c}/V_{a,c} \simeq \begin{cases} X_{a,f_c(a)} & \text{if } a \in \Delta \cup \{-\theta\} \\ 0 & \text{otherwise} \end{cases}$, where the quotient groups $X_{a,f_c(a)}$ are defined as in Proposition 3.1.11. Applying Corollary 5.2.1, we write $P/\text{Frat}(P) \simeq \prod_{a \in \Delta \cup \{-\theta\}} X_{a,f_c(a)}$. We know by Proposition 3.1.11 that the group $X_{a,f_c(a)}$ is a κ_{L_a} -vector space of dimension 1. The finite field κ_{L_a} is of order p^{mf_a} where f_a denotes the residue degree of the extension L_a/L_d . Thus, we obtain $\dim_{\mathbb{F}_p}(P/\text{Frat}(P)) = \sum_{a \in \Delta \cup \{-\theta\}} mf_a$. It remains to compute $\xi = \sum_{a \in \Delta \cup \{-\theta\}} f_a$. Let $a \in \Delta \cup \{-\theta\}$. If a is a long root, then $L_a = L_d$ and $f_a = 1$. Otherwise $L_a = L'$ and $f_a = f'$.

Suppose that L'/L_d is ramified. We know that θ^D is the highest root of Φ^D with respect to Δ^D . Hence $-\theta^D$ is a long root of Φ^D and $-\theta$ is a short

root. Thus, $L_{-\theta} = L'$, so that $f_{-\theta} = f' = 1$. We have $f_a = 1$ for any simple root $a \in \Delta$. Thus $\xi = \text{Card}(\Delta) + f_{-\theta} = l + 1$.

Suppose that L'/L_d is unramified. We know that θ is the highest root of Φ with respect to Δ . Hence, $-\theta$ is a long root and $L_{-\theta} = L_d$, so that $f_{-\theta} = 1$. We have $f_a = \text{Card}(a)$ where any simple root $a \in \Delta$ is seen as an orbit of absolute simple roots $\alpha \in \tilde{\Delta}$. Thus $\xi = f_{-\theta} + \sum_{a \in \Delta} f_a = 1 + \text{Card}(\tilde{\Delta}) = 1 + n$.

Suppose that Φ is non-reduced of rank $l \geq 2$.

We have a group isomorphism $P/\text{Frat}(P) \simeq \prod_{b \in \Delta \cup \{-\theta\}} U_{b,l_b}/V_b$. We can express each $U_{b,l_b}/V_b$ in terms of $X_{b,l}$ (and of $X_{2b,2l}$ if $b \in \{a, -\theta\}$ is a multipliable root).

First case: b is non-multipliable. In this case, we have $V_b = U_{b,f_c(b)+}$. By 3.1.11, we know that $U_{b,f_c(b)}/U_{b,f_c(b)+} = X_{b,f_c(b)}$ is a κ_{L_b} -vector space of dimension 1, hence a \mathbf{F}_p -vector space of dimension $f'm$.

Second case: b is multipliable and L_b/L_{2b} is ramified. By Lemmas 3.1.13 and 2.1.13, we know that $U_{b,f_c(b)}/V_b = U_{b,f_c(b)}/U_{b,f_c(b)+} = X_{b,f_c(b)}$ is a $\kappa_{L_a} \simeq \kappa_{L_d}$ -vector space of dimension 1, hence a \mathbf{F}_p -vector space of dimension $m = f'm$.

Third case: b is multipliable, L_b/L_{2b} is unramified and $f'_c(b) \notin \Gamma'_a$. By Proposition 3.1.11 and Lemma 3.1.13, we know that $U_{b,f_c(b)}/V_b = U_{b,f_c(b)}/U_{b,f_c(b)+} = X_{2b,2f_c(b)}$ is a $\kappa_{L_{2b}}$ -vector space of dimension 1, hence a \mathbf{F}_p -vector space of dimension m .

Fourth case: b is multipliable, L_b/L_{2b} is unramified and $f'_c(b) \in \Gamma'_a$. By Proposition 3.1.11, we know that $U_{b,f_c(b)}/V_b = U_{b,f_c(b)}/(U_{b,f_c(b)+} + U_{2b,2f_c(b)}) = X_{b,f_c(b)}/X_{2b,2f_c(b)}$ is a κ_{L_b} -vector space of dimension 1, hence a \mathbf{F}_p -vector space of dimension $2m = f'm$.

Furthermore, we note that we have the alternative: either $f_c(a) \in \Gamma'_a$ and $f_c(-\theta) \notin \Gamma'_{-\theta}$, or $f_c(a) \notin \Gamma'_a$ and $f_c(-\theta) \in \Gamma'_{-\theta}$. Hence, the sum of dimensions over \mathbb{F}_p of $U_{a,f_c(a)}/V_a$ and $U_{-\theta,f_c(-\theta)}/V_{-\theta}$ is always equal to $(f' + 1)fm$.

Since there are $l - 1$ non-multipliable simple roots, we get $d(P) = mf'(l - 1) + (1 + f') = m(lf' + 1)$. Let ξ be such that $d(P) = m\xi$. If L'/L_d is unramified, then $f' = 2$ and $\xi = 2l + 1 = n + 1$. If L'/L_d is ramified, then $f' = 1$ and $\xi = l + 1$.

(2) Suppose that Φ is non-reduced of rank 1. In this case, we cannot apply Theorem 5.1.2 and its Corollary. Let $H = U_{-a,\frac{1}{2}}T(K)_b^+U_{a,0}$ be a maximal pro- p subgroup of $G(K) \simeq \text{SU}(h)(K)$, so that $\varepsilon = 0$. Let $l'' = \max(1, 3) = 3$.

Suppose that L/L_2 is unramified. By Lemma 2.3.12, by Lemma 2.3.4 and by Proposition 2.3.1, we have:

$$U_{-2a,2}U_{-a,\frac{3}{2}}T(K)_b^{l''}U_{a,1}U_{2a,0} \subset [H, H]H^p \subset U_{-2a,2}U_{-a,1}T(K)_b^+U_{a,\frac{1}{2}}U_{2a,0}$$

On the one hand, thanks to computation with the quotient groups $X_{a,l}$, we get the L_2 -vector spaces $U_{a,0}/U_{a,\frac{1}{2}}U_{2a,0} \simeq X_{a,0}/X_{2a,0}$ of dimension $d(a, 0) = 2$ and $U_{-a,\frac{1}{2}}/U_{-2a,2}U_{-a,1} \simeq X_{-a,\frac{1}{2}}$ of dimension $d(-a, \frac{1}{2}) + d(-2a, 1) = 0 + 1 = 1$. Hence $d(H) \geq 3m$. On the other hand, $U_{a,0}/U_{a,1}U_{2a,0}$ have to be isomorphic to a subgroup of $X_{a,0}/X_{2a,0} \oplus X_{a,\frac{1}{2}}/X_{2a,1}$, of dimension $d(a, 0) + d(a, \frac{1}{2}) = 2$ as κ_{L_2} -vector space. In the same way, $U_{-a,\frac{1}{2}}/U_{-2a,2}U_{-a,\frac{3}{2}}$ is isomorphic to a subgroup of $X_{-a,\frac{1}{2}} \oplus X_{-a,1}/X_{-2a,-2}$, of dimension $d(-a, \frac{1}{2}) + d(-2a, 1) + d(-a, 1) = 0 + 1 + 2 = 3$. Finally, $T(K)_b^+/T(K)_b^{l''}$ is of dimension $2(l'' - 1) = 4$. Thus $d(H) \leq m(5 + 4) = 9m$.

Suppose that L/L_2 is ramified. By Lemma 2.3.12, by Lemma 2.3.4 and by Proposition 2.3.1, we have:

$$U_{-2a,3}U_{-a,2}T(K)_b^{l''}U_{a,\frac{3}{2}}U_{2a,1} \subset [H, H]H^p \subset U_{-2a,3}U_{-a,1}T(K)_b^+U_{a,\frac{1}{2}}U_{2a,1}$$

On the one hand, thanks to computation with the quotient groups $X_{a,l}$, we get the L_2 -vector spaces $U_{a,0}/U_{a,\frac{1}{2}}U_{2a,1} \simeq X_{a,0}$ of dimension $d(a, 0) + d(2a, 0) = 1 + 0$ and $U_{-a,\frac{1}{2}}/U_{-2a,3}U_{-a,1} \simeq X_{-a,\frac{1}{2}}$ of dimension $d(-a, \frac{1}{2}) + d(-2a, 1) = 0 + 1 = 1$. Hence $d(H) \geq 2m$. On the other hand, $U_{a,0}/U_{a,\frac{3}{2}}U_{2a,1}$ have to be isomorphic to a subgroup of $X_{a,0} \oplus X_{a,\frac{1}{2}}/X_{2a,1} \oplus X_{a,1}/X_{2a,2}$, of dimension $d(a, 0) + d(2a, 0) + d(a, \frac{1}{2}) + d(a, 1) = 1 + 0 + 0 + 1 = 2$ as κ_{L_2} -vector space. In the same way, $U_{-a,\frac{1}{2}}/U_{-2a,3}U_{-a,2}$ is isomorphic to a subgroup of $X_{-a,\frac{1}{2}} \oplus X_{-a,1} \oplus X_{-a,\frac{3}{2}}/X_{2a,3}$, of dimension $d(-a, \frac{1}{2}) + d(-2a, 1) + d(-a, 1) + d(-2a, 2) + d(-a, \frac{3}{2}) = 0 + 1 + 1 + 0 + 0 = 2$. Finally, $T(K)_b^+/T(K)_b^{l''}$ is of dimension $(l'' - 1) = 2$. Thus $d(H) \leq m(4 + 2) = 6m$. \square

5.2.4 Remark (Generating set in terms of root groups). A generating set of $P/\text{Frat}(P)$ always come from a topologically generating set of P . Hence, when the relative root system Φ is reduced, a system of generators of P is given by:

$$\left\{ x_a(\lambda_i), 1 \leq i \leq m \text{ and } a \in \Delta \right\} \cup \left\{ x_{-\theta}(\lambda_i \varpi_{L'}), 1 \leq i \leq m \right\}$$

where $(\lambda_i)_{1 \leq i \leq m}$ is a family of elements of \mathcal{O}_{L_d} such that $(\lambda_i \mathcal{O}_{L_d} / \mathfrak{m}_{L_d})_{1 \leq i \leq m}$ is a basis of κ_{L_d} ; the root θ is chosen as in Section 3.1; and $\varpi_{L'}$ is a uniformizer of $\mathcal{O}_{L'}$.
